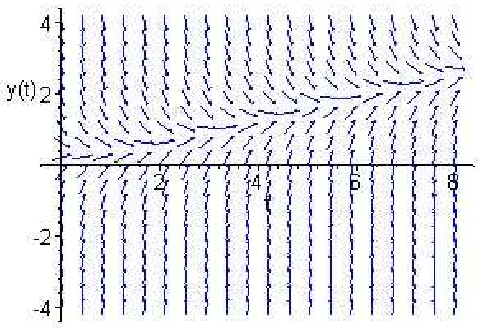
CHAPTER

2

First Order Differential Equations

2.1

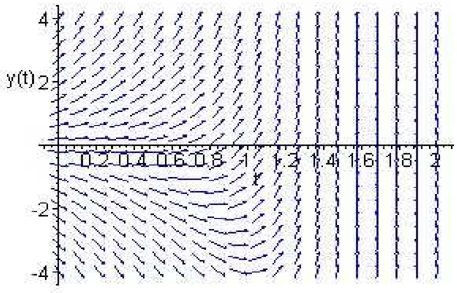
1.(a)



(b) Based on the direction field, all solutions seem to converge to a specific increasing function.

(c) The integrating factor is $\mu(t) = e^{3t}$, and hence $y(t) = t/3 - 1/9 + e^{-2t} + c\,e^{-3t}$. It follows that all solutions converge to the function $y_1(t) = t/3 - 1/9$.

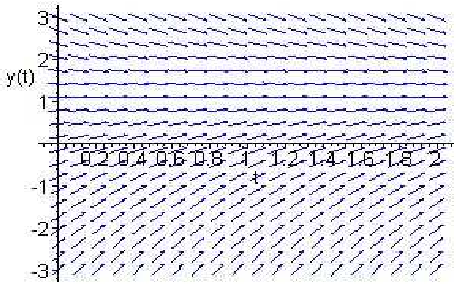
2.(a)



(b) All solutions eventually have positive slopes, and hence increase without bound.

(c) The integrating factor is $\mu(t) = e^{-2t}$, and hence $y(t) = t^3e^{2t}/3 + c\,e^{2t}$. It is evident that all solutions increase at an exponential rate.

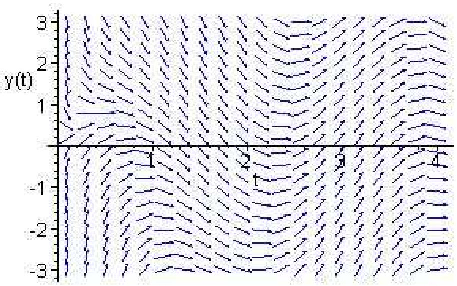
3.(a)



(b) All solutions seem to converge to the function $y_0(t) = 1$.

(c) The integrating factor is $\mu(t) = e^t$, and hence $y(t) = t^2e^{-t}/2 + 1 + c\,e^{-t}$. It is clear that all solutions converge to the specific solution $y_0(t) = 1$.

4.(a)



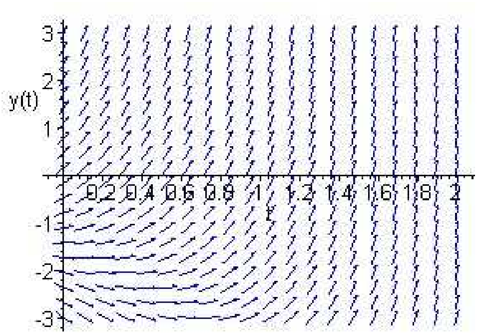
(b) Based on the direction field, the solutions eventually become oscillatory.

(c) The integrating factor is $\mu(t) = t$, and hence the general solution is

$$y(t) = \frac{3\cos 2t}{4t} + \frac{3}{2}\sin 2t + \frac{c}{t}$$

in which c is an arbitrary constant. As t becomes large, all solutions converge to the function $y_1(t) = 3(\sin 2t)/2$.

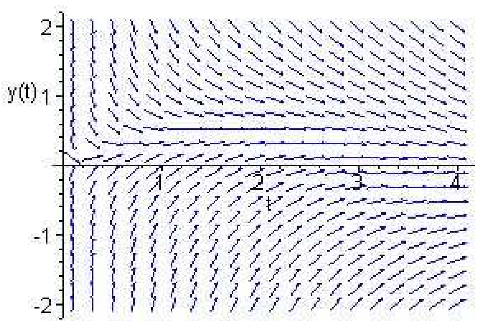
5.(a)



(b) All solutions eventually have positive slopes, and hence increase without bound.

(c) The integrating factor is $\mu(t) = e^{-\int 2dt} = e^{-2t}$. The differential equation can be written as $e^{-2t}y' - 2e^{-2t}y = 3e^{-t}$, that is, $(e^{-2t}y)' = 3e^{-t}$. Integration of both sides of the equation results in the general solution $y(t) = -3e^t + c\,e^{2t}$. It follows that all solutions will increase exponentially.

6.(a)



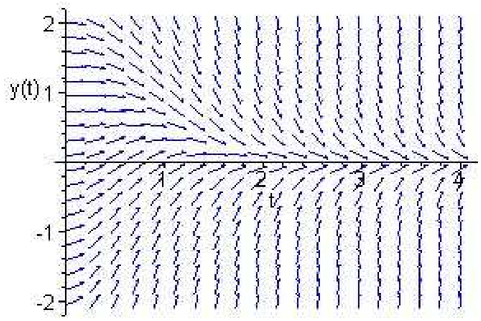
(b) All solutions seem to converge to the function $y_0(t) = 0$.

(c) The integrating factor is $\mu(t) = t^2$, and hence the general solution is

$$y(t) = -\frac{\cos t}{t} + \frac{\sin t}{t^2} + \frac{c}{t^2}$$

in which c is an arbitrary constant $(t > 0)$. As t becomes large, all solutions converge to the function $y_0(t) = 0$.

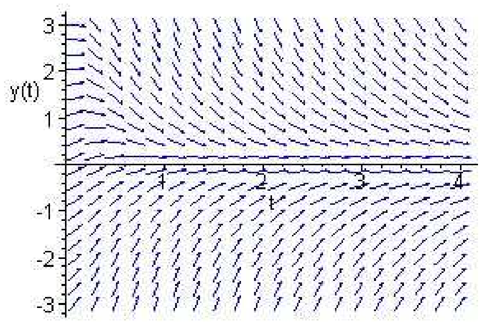
7.(a)



(b) All solutions seem to converge to the function $y_0(t) = 0$.

(c) The integrating factor is $\mu(t) = e^{t^2}$, and hence $y(t) = t^2 e^{-t^2} + c\,e^{-t^2}$. It is clear that all solutions converge to the function $y_0(t) = 0$.

8.(a)



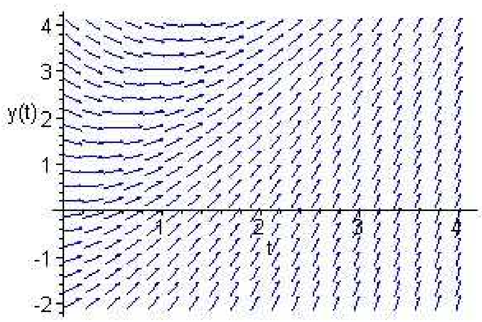
(b) All solutions seem to converge to the function $y_0(t) = 0$.

(c) Since $\mu(t) = (1 + t^2)^2$, the general solution is

$$y(t) = \frac{\arctan t + c}{(1 + t^2)^2}.$$

It follows that all solutions converge to the function $y_0(t) = 0$.

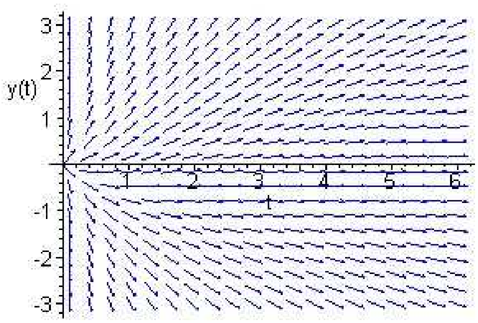
9.(a)



(b) All solutions eventually have positive slopes, and hence increase without bound.

(c) The integrating factor is $\mu(t) = e^{\int \frac{1}{2} dt} = e^{t/2}$. The differential equation can be written as $e^{t/2}y' + e^{t/2}y/2 = 3t\, e^{t/2}/2$, that is, $(e^{t/2}\, y/2)' = 3t\, e^{t/2}/2$. Integration of both sides of the equation results in the general solution $y(t) = 3t - 6 + c\, e^{-t/2}$. All solutions approach the specific solution $y_0(t) = 3t - 6$.

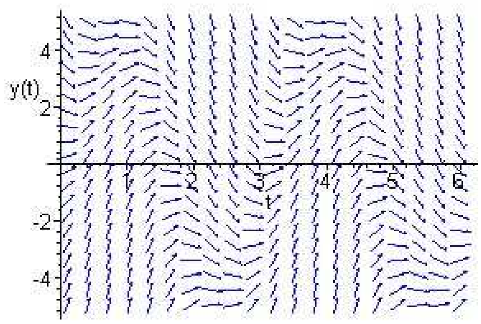
10.(a)



(b) For $y > 0$, the slopes are all positive, and hence the corresponding solutions increase without bound. For $y < 0$, almost all solutions have negative slopes, and hence solutions tend to decrease without bound.

(c) First divide both sides of the equation by t $(t > 0)$. From the resulting standard form, the integrating factor is $\mu(t) = e^{-\int \frac{1}{t} dt} = 1/t$. The differential equation can be written as $y'/t - y/t^2 = t\, e^{-t}$, that is, $(\,y/t)' = t\, e^{-t}$. Integration leads to the general solution $y(t) = -te^{-t} + c\,t$. For $c \neq 0$, solutions diverge, as implied by the direction field. For the case $c = 0$, the specific solution is $y(t) = -te^{-t}$, which evidently approaches zero as $t \to \infty$.

11.(a)

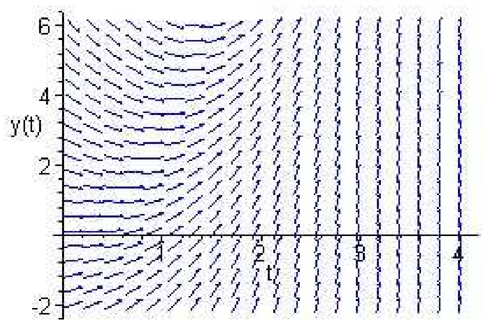


(b) The solutions appear to be oscillatory.

(c) The integrating factor is $\mu(t) = e^t$, and hence $y(t) = \sin 2t - 2\cos 2t + c\,e^{-t}$. It is evident that all solutions converge to the specific solution

$$y_0(t) = \sin 2t - 2\cos 2t.$$

12.(a)



(b) All solutions eventually have positive slopes, and hence increase without bound.

(c) The integrating factor is $\mu(t) = e^{t/2}$. The differential equation can be written as $e^{t/2}y' + e^{t/2}y/2 = 3t^2/2$, that is, $(e^{t/2}\,y/2)' = 3t^2/2$. Integration of both sides of the equation results in the general solution $y(t) = 3t^2 - 12t + 24 + c\,e^{-t/2}$. It follows that all solutions converge to the specific solution $y_0(t) = 3t^2 - 12t + 24$.

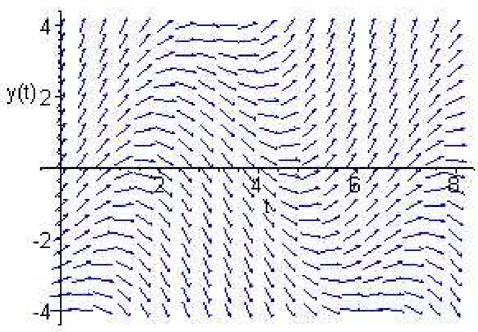
14. The integrating factor is $\mu(t) = e^{2t}$. After multiplying both sides by $\mu(t)$, the equation can be written as $(e^{2t}\,y)' = t$. Integrating both sides of the equation results in the general solution $y(t) = t^2e^{-2t}/2 + c\,e^{-2t}$. Invoking the specified condition, we require that $e^{-2}/2 + c\,e^{-2} = 0$. Hence $c = -1/2$, and the solution to the initial value problem is $y(t) = (t^2 - 1)e^{-2t}/2$.

16. The integrating factor is $\mu(t) = e^{\int \frac{2}{t}dt} = t^2$. Multiplying both sides by $\mu(t)$, the equation can be written as $(t^2\, y)' = \cos t$. Integrating both sides of the equation results in the general solution $y(t) = \sin t/t^2 + c\,t^{-2}$. Substituting $t = \pi$ and setting the value equal to zero gives $c = 0$. Hence the specific solution is $y(t) = \sin t/t^2$.

17. The integrating factor is $\mu(t) = e^{-2t}$, and the differential equation can be written as $(e^{-2t}\, y)' = 1$. Integrating, we obtain $e^{-2t}\, y(t) = t + c$. Invoking the specified initial condition results in the solution $y(t) = (t+2)e^{2t}$.

19. After writing the equation in standard form, we find that the integrating factor is $\mu(t) = e^{\int \frac{4}{t}dt} = t^4$. Multiplying both sides by $\mu(t)$, the equation can be written as $(t^4\, y)' = t\, e^{-t}$. Integrating both sides results in $t^4 y(t) = -(t+1)e^{-t} + c$. Letting $t = -1$ and setting the value equal to zero gives $c = 0$. Hence the specific solution of the initial value problem is $y(t) = -(t^{-3} + t^{-4})e^{-t}$.

21.(a)



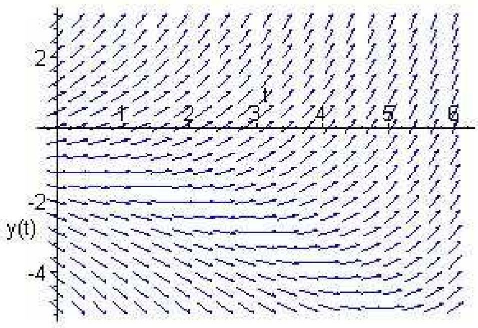
The solutions appear to diverge from an apparent oscillatory solution. From the direction field, the critical value of the initial condition seems to be $a_0 = -1$. For $a > -1$, the solutions increase without bound. For $a < -1$, solutions decrease without bound.

(b) The integrating factor is $\mu(t) = e^{-t/2}$. The general solution of the differential equation is $y(t) = (8\sin t - 4\cos t)/5 + c\,e^{t/2}$. The solution is sinusoidal as long as $c = 0$. The initial value of this sinusoidal solution is

$$a_0 = (8\sin(0) - 4\cos(0))/5 = -4/5.$$

(c) See part (b).

22.(a)

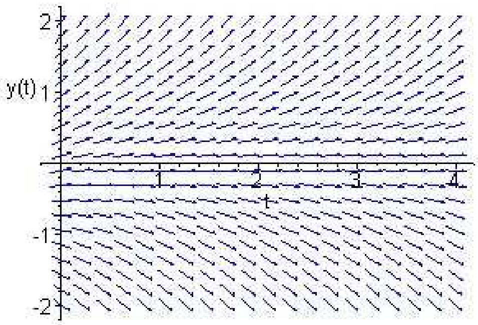


All solutions appear to eventually increase without bound. The solutions initially increase or decrease, depending on the initial value a. The critical value seems to be $a_0 = -1$.

(b) The integrating factor is $\mu(t) = e^{-t/2}$, and the general solution of the differential equation is $y(t) = -3e^{t/3} + c\, e^{t/2}$. Invoking the initial condition $y(0) = a$, the solution may also be expressed as $y(t) = -3e^{t/3} + (a+3)\, e^{t/2}$. The critical value is $a_0 = -3$.

(c) For $a_0 = -3$, the solution is $y(t) = -3e^{t/3}$, which diverges to $-\infty$ as $t \to \infty$.

23.(a)



Solutions appear to grow infinitely large in absolute value, with signs depending on the initial value $y(0) = a_0$. The direction field appears horizontal for $a_0 \approx -1/8$.

(b) Dividing both sides of the given equation by 3, the differential equation for the integrating factor is

$$\frac{d\mu}{dt} = -\frac{2}{3}\,\mu\,.$$

Hence the integrating factor is $\mu(t) = e^{-2t/3}$. Multiplying both sides of the original differential equation by $\mu(t)$ and integrating results in

$$y(t) = \frac{2\, e^{2t/3} - 2\, e^{-\pi t/2} + a(4+3\pi)\, e^{2t/3}}{4+3\pi}\,.$$

The qualitative behavior of the solution is determined by the terms containing $e^{2t/3}$:

$$2\,e^{2t/3} + a(4+3\pi)\,e^{2t/3}$$

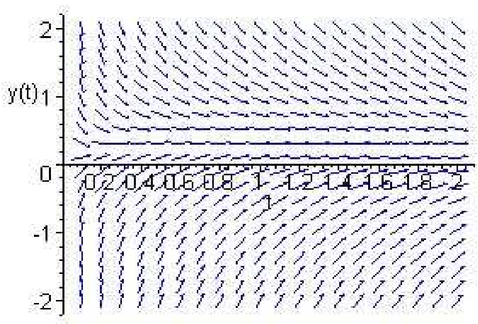
The nature of the solutions will change when $2 + a(4+3\pi) = 0$. Thus the critical initial value is $a_0 = -2/(4+3\pi)$.

(c) In addition to the behavior described in part (a), when $y(0) = -2/(4+3\pi)$,

$$y(t) = \frac{-2\,e^{-\pi t/2}}{4+3\pi}\,,$$

and that specific solution will converge to $y = 0$.

24.(a)

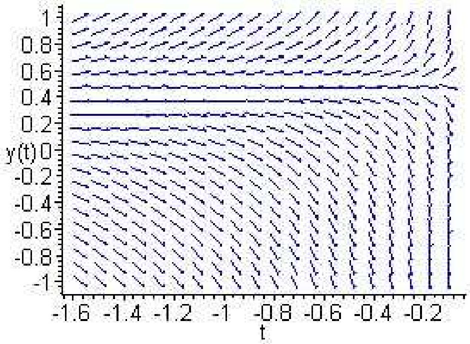


As $t \to 0$, solutions increase without bound if $y(1) = a > .4$, and solutions decrease without bound if $y(1) = a < .4$.

(b) The integrating factor is $\mu(t) = e^{\int \frac{t+1}{t}\,dt} = t\,e^{t}$. The general solution of the differential equation is $y(t) = t\,e^{-t} + c\,e^{-t}/t$. Since $y(1) = a$, we have that $1 + c = ae$. That is, $c = ae - 1$. Hence the solution can also be expressed as $y(t) = t\,e^{-t} + (ae-1)\,e^{-t}/t$. For small values of t , the second term is dominant. Setting $ae - 1 = 0$, the critical value of the parameter is $a_0 = 1/e$.

(c) For $a > 1/e$, solutions increase without bound. For $a < 1/e$, solutions decrease without bound. When $a = 1/e$, the solution is $y(t) = t\,e^{-t}$, which approaches 0 as $t \to 0$.

25.(a)



As $t \to 0$, solutions increase without bound if $y(1) = a > .4$, and solutions decrease without bound if $y(1) = a < .4$.

(b) Given the initial condition $y(-\pi/2) = a$, the solution is

$$y(t) = (a\,\pi^2/4 - \cos\, t)/t^2.$$

Since $\lim_{t\to 0} \cos\, t = 1$, solutions increase without bound if $a > 4/\pi^2$, and solutions decrease without bound if $a < 4/\pi^2$. Hence the critical value is $a_0 = 4/\pi^2 \approx 0.452847$.

(c) For $a = 4/\pi^2$, the solution is $y(t) = (1 - \cos\, t)/t^2$, and $\lim_{t\to 0} y(t) = 1/2$. Hence the solution is bounded.

27. The integrating factor is $\mu(t) = e^{\int \frac{1}{2} dt} = e^{t/2}$. Therefore the general solution is $y(t) = (4\cos t + 8\sin t)/5 + c\, e^{-t/2}$. Invoking the initial condition, the specific solution is $y(t) = (4\cos t + 8\sin t - 9\, e^{t/2})/5$. Differentiating, it follows that

$$y'(t) = (-4\sin t + 8\cos t + 4.5\, e^{-t/2})/5$$
$$y''(t) = (-4\cos t - 8\sin t - 2.25\, e^{-t/2})/5$$

Setting $y'(t) = 0$, the first solution is $t_1 = 1.3643$, which gives the location of the first stationary point. Since $y''(t_1) < 0$, the first stationary point in a local maximum. The coordinates of the point are $(1.3643\,, .82008)$.

28. The integrating factor is $\mu(t) = e^{\int \frac{2}{3} dt} = e^{2t/3}$, and the differential equation can be written as $(e^{2t/3}\, y)' = e^{2t/3} - t\, e^{2t/3}/2$. The general solution is

$$y(t) = (21 - 6t)/8 + c\, e^{-2t/3}.$$

Imposing the initial condition, we have $y(t) = (21 - 6t)/8 + (y_0 - 21/8)e^{-2t/3}$. Since the solution is smooth, the desired intersection will be a point of tangency. Taking the derivative, $y'(t) = -3/4 - (2y_0 - 21/4)e^{-2t/3}/3$. Setting $y'(t) = 0$, the solution is $t_1 = \frac{3}{2} \ln\left[(21 - 8y_0)/9\right]$. Substituting into the solution, the respective value at the stationary point is $y(t_1) = \frac{3}{2} + \frac{9}{4} \ln 3 - \frac{9}{8} \ln(21 - 8y_0)$. Setting this result equal to zero, we obtain the required initial value $y_0 = (21 - 9\, e^{4/3})/8 \approx -1.643$.

29. The integrating factor is $\mu(t) = e^{t/4}$, and the differential equation can be written as $(e^{t/4}\, y)' = 3\, e^{t/4} + 2\, e^{t/4} \cos 2t$. The general solution is

$$y(t) = 12 + (8 \cos 2t + 64 \sin 2t)/65 + c\; e^{-t/4}.$$

Invoking the initial condition, $y(0) = 0$, the specific solution is

$$y(t) = 12 + (8 \cos 2t + 64 \sin 2t - 788\, e^{-t/4})/65\,.$$

As $t \to \infty$, the exponential term will decay, and the solution will oscillate about an average value of 12, with an amplitude of $8/\sqrt{65}$.

31. The integrating factor is $\mu(t) = e^{-3t/2}$, and the differential equation can be written as $(e^{-3t/2}\; y)' = 3t\, e^{-3t/2} + 2\, e^{-t/2}$. The general solution is

$$y(t) = -2t - 4/3 - 4\, e^{t} + c\, e^{3t/2}.$$

Imposing the initial condition, $y(t) = -2t - 4/3 - 4\, e^{t} + (y_0 + 16/3)\, e^{3t/2}$. Now as $t \to \infty$, the term containing $e^{3t/2}$ will dominate the solution. Its sign will determine the divergence properties. Hence the critical value of the initial condition is $y_0 = -16/3$. The corresponding solution, $y(t) = -2t - 4/3 - 4\, e^{t}$, will also decrease without bound.

Note on Problems 34-37:

Let $g(t)$ be given, and consider the function $y(t) = y_1(t) + g(t)$, in which $y_1(t) \to 0$ as $t \to \infty$. Differentiating, $y\,'(t) = y_1'(t) + g\,'(t)$. Letting a be a constant, it follows that $y\,'(t) + ay(t) = y_1'(t) + ay_1(t) + g\,'(t) + ag(t)$. Note that the hypothesis on the function $y_1(t)$ will be satisfied, if $y_1'(t) + ay_1(t) = 0$. That is, $y_1(t) = c\, e^{-at}$. Hence $y(t) = c\, e^{-at} + g(t)$, which is a solution of the equation $y\,' + ay = g\,'(t) + ag(t)$. For convenience, choose $a = 1$.

34. Here $g(t) = 3$, and we consider the linear equation $y\,' + y = 3$. The integrating factor is $\mu(t) = e^{t}$, and the differential equation can be written as $(e^{t}\, y)' = 3e^{t}$. The general solution is $y(t) = 3 + c\, e^{-t}$.

36. Here $g(t) = 2t - 5$. Consider the linear equation $y\,' + y = 2 + 2t - 5$. The integrating factor is $\mu(t) = e^{t}$, and the differential equation can be written as $(e^{t}\, y)' = (2t - 3)e^{t}$. The general solution is $y(t) = 2t - 5 + c\, e^{-t}$.

37. $g(t) = 4 - t^2$. Consider the linear equation $y\,' + y = 4 - 2t - t^2$.The integrating factor is $\mu(t) = e^{t}$, and the equation can be written as $(e^{t}\, y)' = (4 - 2t - t^2)e^{t}$. The general solution is $y(t) = 4 - t^2 + c\, e^{-t}$.

38.(a) Differentiating y and using the fundamental theorem of calculus we obtain that $y' = Ae^{-\int p(t)dt} \cdot (-p(t))$, and then $y' + p(t)y = 0$.

(b) Differentiating y we obtain that

$$y' = A'(t)e^{-\int p(t)dt} + A(t)e^{-\int p(t)dt} \cdot (-p(t)).$$

If this satisfies the differential equation then

$$y' + p(t)y = A'(t)e^{-\int p(t)dt} = g(t)$$

and the required condition follows.

(c) Let us denote $\mu(t) = e^{\int p(t)dt}$. Then clearly $A(t) = \int \mu(t)g(t)dt$, and after substitution $y = \int \mu(t)g(t)dt \cdot (1/\mu(t))$, which is just Eq. (33).

40. We assume a solution of the form

$$y = A(t)e^{-\int \frac{1}{t}dt} = A(t)e^{-\ln t} = A(t)t^{-1},$$

where $A(t)$ satisfies $A'(t) = 3t\cos 2t$. This implies that

$$A(t) = \frac{3\cos 2t}{4} + \frac{3t\sin 2t}{2} + c$$

and the solution is

$$y = \frac{3\cos 2t}{4t} + \frac{3\sin 2t}{2} + \frac{c}{t}.$$

41. First rewrite the differential equation as

$$y' + \frac{2}{t}y = \frac{\sin t}{t}.$$

Assume a solution of the form

$$y = A(t)e^{-\int \frac{2}{t}dt} = A(t)t^{-2},$$

where $A(t)$ satisfies the ODE

$$A'(t) = t \sin t.$$

It follows that $A(t) = \sin t - t\cos t + c$ and thus $y = (\sin t - t\cos t + c)/t^2$.

2.2

2. For $x \neq -1$, the differential equation may be written as

$$y\,dy = \left[x^2/(1+x^3)\right]dx.$$

Integrating both sides, with respect to the appropriate variables, we obtain the relation $y^2/2 = \frac{1}{3}\ln\left|1+x^3\right| + c$. That is, $y(x) = \pm\sqrt{\frac{2}{3}\ln|1+x^3| + c}$.

3. The differential equation may be written as $y^{-2}dy = -\sin x\,dx$. Integrating both sides of the equation, with respect to the appropriate variables, we obtain the relation $-y^{-1} = \cos x + c$. That is, $(c - \cos x)y = 1$, in which c is an arbitrary constant. Solving for the dependent variable, explicitly, $y(x) = 1/(c - \cos x)$.

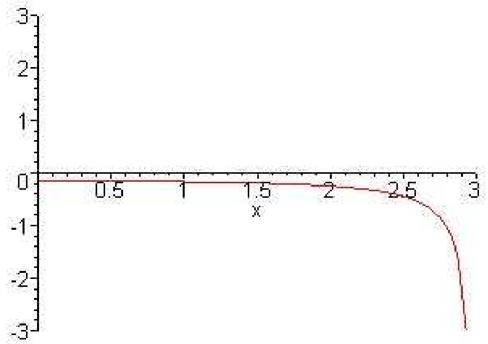
5. Write the differential equation as $\cos^{-2} 2y\,dy = \cos^2 x\,dx$, or $\sec^2 2y\,dy = \cos^2 x\,dx$. Integrating both sides of the equation, with respect to the appropriate variables, we obtain the relation $\tan 2y = \sin x\cos x + x + c$.

7. The differential equation may be written as $(y + e^y)dy = (x - e^{-x})dx$. Integrating both sides of the equation, with respect to the appropriate variables, we obtain the relation $y^2 + 2\,e^y = x^2 + 2\,e^{-x} + c$.

8. Write the differential equation as $(1 + y^2)dy = x^2\,dx$. Integrating both sides of the equation, we obtain the relation $y + y^3/3 = x^3/3 + c$.

9.(a) The differential equation is separable, with $y^{-2}dy = (1 - 2x)dx$. Integration yields $-y^{-1} = x - x^2 + c$. Substituting $x = 0$ and $y = -1/6$, we find that $c = 6$. Hence the specific solution is $y = 1/(x^2 - x - 6)$.

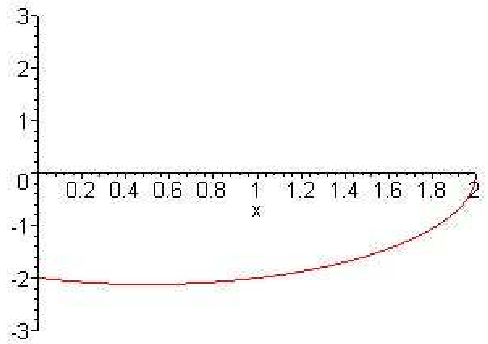
(b)



(c) Note that $x^2 - x - 6 = (x + 2)(x - 3)$. Hence the solution becomes singular at $x = -2$ and $x = 3$, so the interval of existence is $(-2, 3)$.

10.(a) $y(x) = -\sqrt{2x - 2x^2 + 4}$.

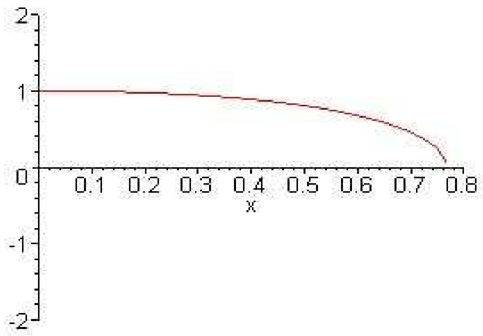
(b)



(c) The interval of existence is $(-1, 2)$.

11.(a) Rewrite the differential equation as $x\,e^x dx = -y\,dy$. Integrating both sides of the equation results in $x\,e^x - e^x = -y^2/2 + c$. Invoking the initial condition, we obtain $c = -1/2$. Hence $y^2 = 2e^x - 2x\,e^x - 1$. The explicit form of the solution is $y(x) = \sqrt{2e^x - 2x\,e^x - 1}$. The positive sign is chosen, since $y(0) = 1$.

(b)

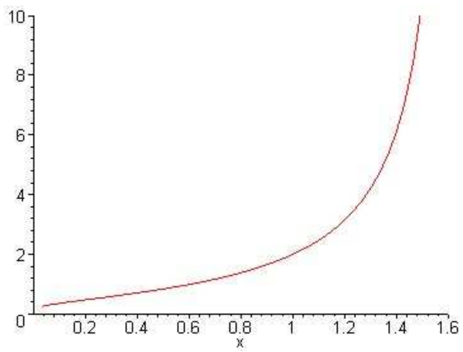


(c) The function under the radical becomes negative near $x \approx -1.7$ and $x \approx 0.77$.

12.(a) Write the differential equation as $r^{-2}dr = \theta^{-1}\,d\theta$. Integrating both sides of the equation results in the relation $-r^{-1} = \ln\,\theta + c$. Imposing the condition $r(1) = 2$, we obtain $c = -1/2$. The explicit form of the solution is

$$r(\theta) = \frac{2}{1 - 2\,\ln\,\theta}.$$

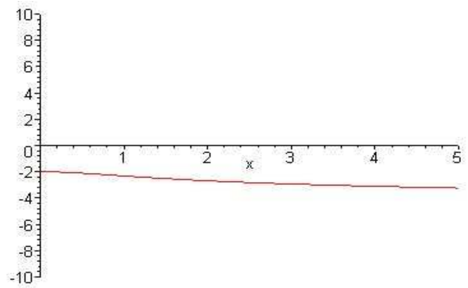
(b)



(c) Clearly, the solution makes sense only if $\theta > 0$. Furthermore, the solution becomes singular when $\ln\,\theta = 1/2$, that is, $\theta = \sqrt{e}$.

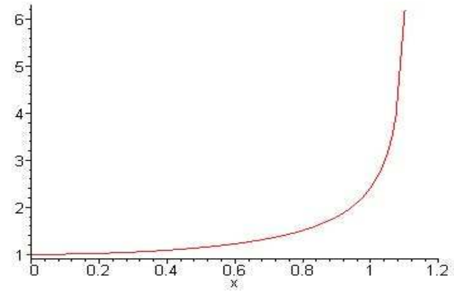
13.(a) $y(x) = -\sqrt{2\,\ln(1+x^2)+4}$.

(b)



14.(a) Write the differential equation as $y^{-3}dy = x(1+x^2)^{-1/2}\,dx$. Integrating both sides of the equation, with respect to the appropriate variables, we obtain the relation $-y^{-2}/2 = \sqrt{1+x^2} + c$. Imposing the initial condition, we obtain $c = -3/2$. Hence the specific solution can be expressed as $y^{-2} = 3 - 2\sqrt{1+x^2}$. The explicit form of the solution is $y(x) = 1/\sqrt{3-2\sqrt{1+x^2}}$. The positive sign is chosen to satisfy the initial condition.

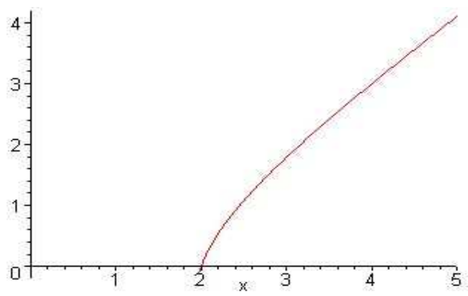
(b)



(c) The solution becomes singular when $2\sqrt{1+x^2} = 3$. That is, at $x = \pm\sqrt{5}/2$.

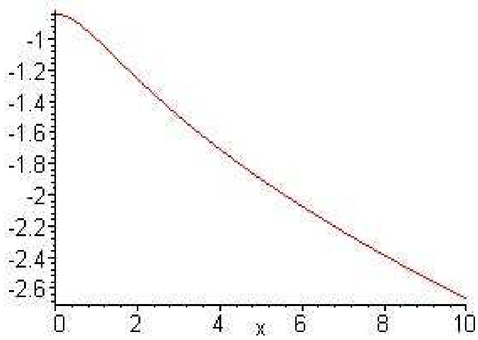
15.(a) $y(x) = -1/2 + \sqrt{x^2 - 15/4}$.

(b)



16.(a) Rewrite the differential equation as $4y^3dy = x(x^2+1)dx$. Integrating both sides of the equation results in $y^4 = (x^2+1)^2/4 + c$. Imposing the initial condition, we obtain $c = 0$. Hence the solution may be expressed as $(x^2+1)^2 - 4y^4 = 0$. The explicit form of the solution is $y(x) = -\sqrt{(x^2+1)/2}$. The sign is chosen based on $y(0) = -1/\sqrt{2}$.

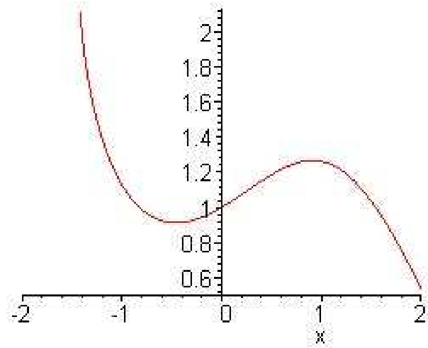
(b)



(c) The solution is valid for all $x \in \mathbb{R}$.

17.(a) $y(x) = 5/2 - \sqrt{x^3 - e^x + 13/4}$.

(b)



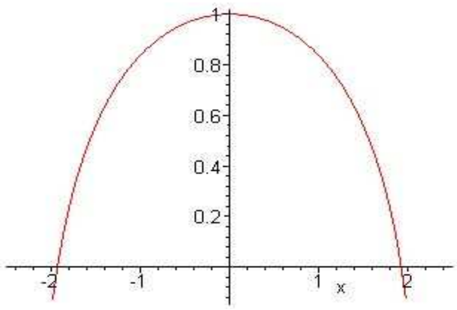
(c) The solution is valid for approximately $-1.45 < x < 4.63$. These values are found by estimating the roots of $4x^3 - 4e^x + 13 = 0$.

18.(a) Write the differential equation as $(3+4y)dy = (e^{-x} - e^x)dx$. Integrating both sides of the equation, with respect to the appropriate variables, we obtain the relation $3y + 2y^2 = -(e^x + e^{-x}) + c$. Imposing the initial condition, $y(0) = 1$, we obtain $c = 7$. Thus, the solution can be expressed as $3y + 2y^2 = -(e^x + e^{-x}) + 7$. Now by completing the square on the left hand side,

$$2(y+3/4)^2 = -(e^x + e^{-x}) + 65/8.$$

Hence the explicit form of the solution is $y(x) = -3/4 + \sqrt{65/16 - \cosh x}$.

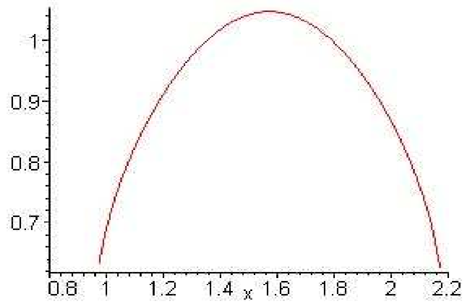
(b)



(c) Note the $65 - 16\cosh x \geq 0$ as long as $|x| > 2.1$ (approximately). Hence the solution is valid on the interval $-2.1 < x < 2.1$.

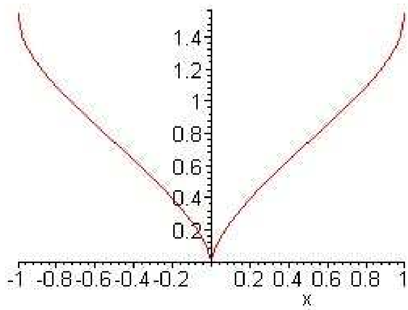
19.(a) $y(x) = (\pi - \arcsin(3\cos^2 x))/3$.

(b)



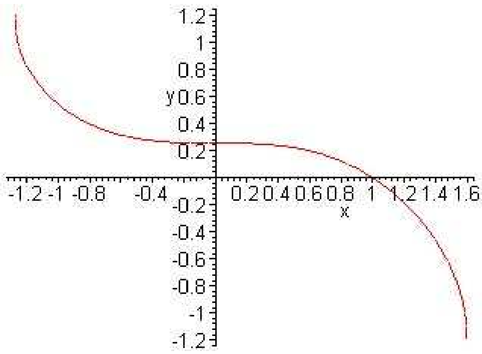
20.(a) Rewrite the differential equation as $y^2dy = \arcsin x/\sqrt{1-x^2}\,dx$. Integrating both sides of the equation results in $y^3/3 = (\arcsin x)^2/2 + c$. Imposing the condition $y(0) = 1$, we obtain $c = 1/3$. The explicit form of the solution is $y(x) = (3(\arcsin x)^2/2 + 1)^{1/3}$.

(b)



(c) Since $\arcsin x$ is defined for $-1 \le x \le 1$, this is the interval of existence.

22. The differential equation can be written as $(3y^2 - 4)dy = 3x^2 dx$. Integrating both sides, we obtain $y^3 - 4y = x^3 + c$. Imposing the initial condition, the specific solution is $y^3 - 4y = x^3 - 1$. Referring back to the differential equation, we find that $y' \to \infty$ as $y \to \pm 2/\sqrt{3}$. The respective values of the abscissas are $x \approx -1.276$, 1.598.



Hence the solution is valid for $-1.276 < x < 1.598$.

24. Write the differential equation as $(3 + 2y)dy = (2 - e^x)dx$. Integrating both sides, we obtain $3y + y^2 = 2x - e^x + c$. Based on the specified initial condition, the solution can be written as $3y + y^2 = 2x - e^x + 1$. Completing the square, it follows that

$$y(x) = -3/2 + \sqrt{2x - e^x + 13/4}.$$

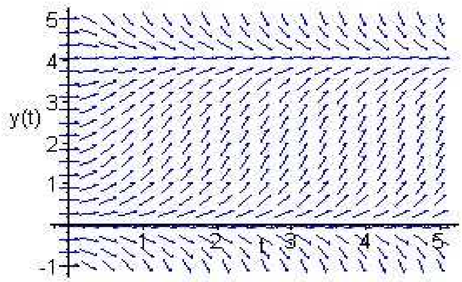
The solution is defined if $2x - e^x + 13/4 \ge 0$, that is, $-1.5 \le x \le 2$ (approximately). In that interval, $y' = 0$, for $x = \ln 2$. It can be verified that $y''(\ln 2) < 0$. In fact, $y''(x) < 0$ on the interval of definition. Hence the solution attains a global maximum at $x = \ln 2$.

26. The differential equation can be written as $(1 + y^2)^{-1}dy = 2(1 + x)dx$. Integrating both sides of the equation, we obtain $\arctan y = 2x + x^2 + c$. Imposing the given initial condition, the specific solution is $\arctan y = 2x + x^2$. Therefore, $y = \tan(2x + x^2)$. Observe that the solution is defined as long as $-\pi/2 < 2x + x^2 < \pi/2$. It is easy to see that $2x + x^2 \ge -1$. Furthermore, $2x + x^2 = \pi/2$ for $x \approx -2.6$ and 0.6. Hence the solution is valid on the interval $-2.6 < x < 0.6$. Referring back to the differential equation, the solution is stationary at $x = -1$. Since $y''(x) > 0$ on the entire interval of definition, the solution attains a global minimum at $x = -1$.

28.(a) Write the differential equation as $y^{-1}(4 - y)^{-1}dy = t(1 + t)^{-1}dt$. Integrating both sides of the equation, we obtain $\ln |y| - \ln |y - 4| = 4t - 4\ln|1 + t| + c$. Taking the exponential of both sides $|y/(y - 4)| = c\,e^{4t}/(1 + t)^4$. It follows that as $t \to \infty$, $|y/(y - 4)| = |1 + 4/(y - 4)| \to \infty$. That is, $y(t) \to 4$.

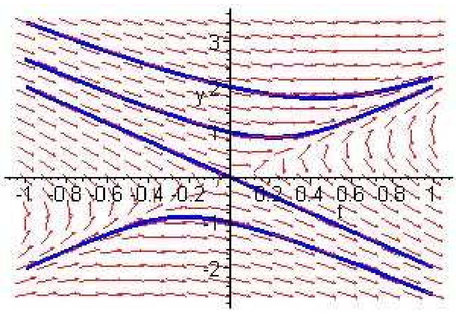
(b) Setting $y(0) = 2$, we obtain that $c = 1$. Based on the initial condition, the solution may be expressed as $y/(y - 4) = -e^{4t}/(1 + t)^4$. Note that $y/(y - 4) < 0$, for all $t \geq 0$. Hence $y < 4$ for all $t \geq 0$. Referring back to the differential equation, it follows that y' is always positive. This means that the solution is monotone increasing. We find that the root of the equation $e^{4t}/(1+t)^4 = 399$ is near $t = 2.844$.

(c) Note the $y(t) = 4$ is an equilibrium solution. Examining the local direction field,

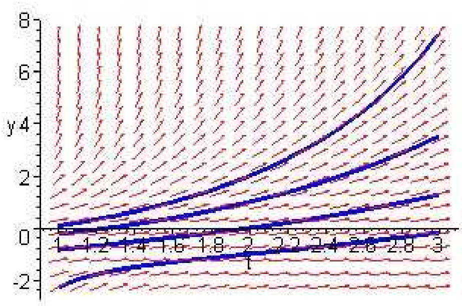


we see that if $y(0) > 0$, then the corresponding solutions converge to $y = 4$. Referring back to part (a), we have $y/(y-4) = [y_0/(y_0-4)]\, e^{4t}/(1+t)^4$, for $y_0 \neq 4$. Setting $t = 2$, we obtain $y_0/(y_0-4) = (3/e^2)^4 y(2)/(y(2)-4)$. Now since the function $f(y) = y/(y-4)$ is monotone for $y < 4$ and $y > 4$, we need only solve the equations $y_0/(y_0-4) = -399(3/e^2)^4$ and $y_0/(y_0-4) = 401(3/e^2)^4$. The respective solutions are $y_0 = 3.6622$ and $y_0 = 4.4042$.

30.(f)



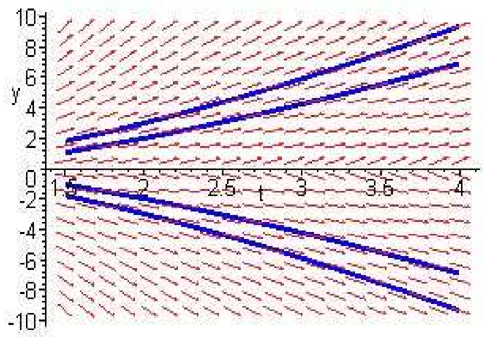
31.(c)



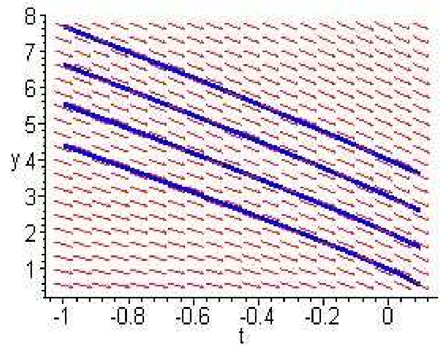
32.(a) Observe that $(x^2 + 3y^2)/2xy = \frac{1}{2}(y/x)^{-1} + \frac{3}{2}(y/x)$. Hence the differential equation is homogeneous.

(b) The substitution $y = x\,v$ results in $v + x\,v' = (x^2 + 3x^2v^2)/2x^2v$. The transformed equation is $v' = (1 + v^2)/2xv$. This equation is separable, with general solution $v^2 + 1 = c\,x$. In terms of the original dependent variable, the solution is $x^2 + y^2 = c\,x^3$.

(c)



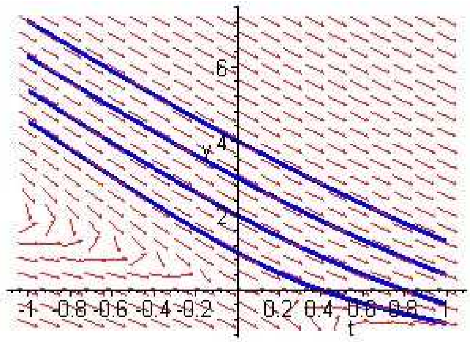
33.(c)



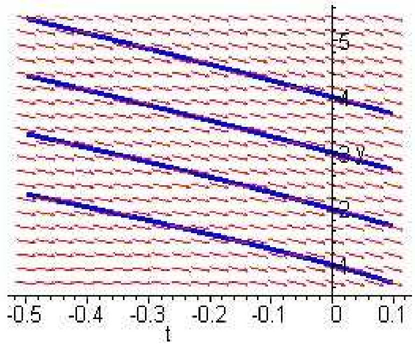
34.(a) Observe that $-(4x + 3y)/(2x + y) = -2 - \frac{y}{x}\left[2 + \frac{y}{x}\right]^{-1}$. Hence the differential equation is homogeneous.

(b) The substitution $y = x\,v$ results in $v + x\,v' = -2 - v/(2 + v)$. The transformed equation is $v' = -(v^2 + 5v + 4)/(2 + v)x$. This equation is separable, with general solution $(v + 4)^2\,|v + 1| = c/x^3$. In terms of the original dependent variable, the solution is $(4x + y)^2\,|x + y| = c$.

(c)



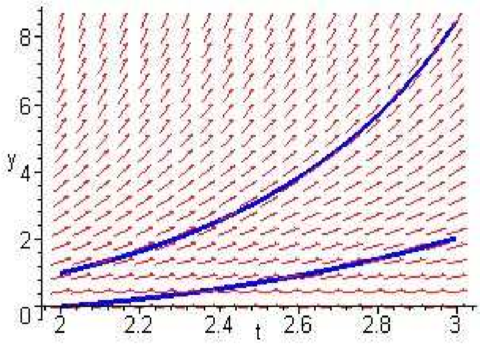
35.(c)



36.(a) Divide by x^2 to see that the equation is homogeneous. Substituting $y = x\,v$, we obtain $x\,v' = (1+v)^2$. The resulting differential equation is separable.

(b) Write the equation as $(1+v)^{-2}dv = x^{-1}dx$. Integrating both sides of the equation, we obtain the general solution $-1/(1+v) = \ln|x| + c$. In terms of the original dependent variable, the solution is $y = x\,(c - \ln|x|)^{-1} - x$.

(c)



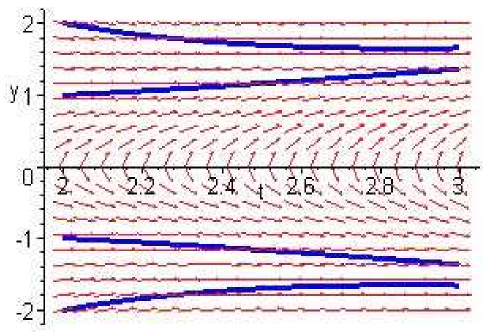
37.(a) The differential equation can be expressed as $y' = \frac{1}{2}(y/x)^{-1} - \frac{3}{2}(y/x)$. Hence the equation is homogeneous. The substitution $y = xv$ results in

$$xv' = (1 - 5v^2)/2v.$$

Separating variables, we have $2vdv/(1 - 5v^2) = dx/x$.

(b) Integrating both sides of the transformed equation yields $-(\ln|1 - 5v^2|)/5 = \ln|x| + c$, that is, $1 - 5v^2 = c/|x|^5$. In terms of the original dependent variable, the general solution is $5y^2 = x^2 - c/|x|^3$.

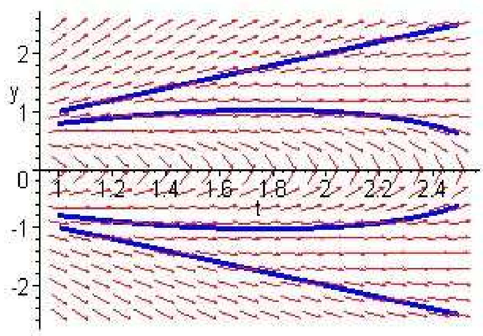
(c)



38.(a) The differential equation can be expressed as $y' = \frac{3}{2}(y/x) - \frac{1}{2}(y/x)^{-1}$. Hence the equation is homogeneous. The substitution $y = x\,v$ results in $x\,v' = (v^2 - 1)/2v$, that is, $2vdv/(v^2 - 1) = dx/x$.

(b) Integrating both sides of the transformed equation yields $\ln\left|v^2 - 1\right| = \ln|x| + c$, that is, $v^2 - 1 = c\,|x|$. In terms of the original dependent variable, the general solution is $y^2 = c\,x^2\,|x| + x^2$.

(c)



2.3

1. Let $Q(t)$ be the amount of dye in the tank at time t. Clearly, $Q(0) = 200$ g. The differential equation governing the amount of dye is

$$Q'(t) = -2\frac{Q(t)}{200}.$$

The solution of this separable equation is $Q(t) = Q(0)e^{-t/100} = 200e^{-t/100}$. We need the time T such that $Q(T) = 2$ g. This means we have to solve $2 = 200e^{-T/100}$ and we obtain that $T = -100\ln(1/100) = 100\ln 100 \approx 460.5$ min.

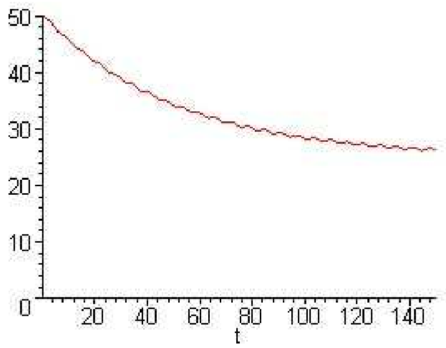
5.(a) Let Q be the amount of salt in the tank. Salt enters the tank of water at a rate of $2\,\frac{1}{4}(1+\frac{1}{2}\sin t) = \frac{1}{2}+\frac{1}{4}\sin t$ oz/min. It leaves the tank at a rate of $2\,Q/100$ oz/min. Hence the differential equation governing the amount of salt at any time is

$$\frac{dQ}{dt} = \frac{1}{2}+\frac{1}{4}\sin t - Q/50\,.$$

The initial amount of salt is $Q_0 = 50$ oz. The governing ODE is linear, with integrating factor $\mu(t) = e^{t/50}$. Write the equation as $(e^{t/50}Q)' = e^{t/50}(\frac{1}{2}+\frac{1}{4}\sin t)$. The specific solution is

$$Q(t) = 25 + (12.5\sin t - 625\cos t + 63150\,e^{-t/50})/2501 \quad \text{oz.}$$

(b)



(c) The amount of salt approaches a steady state, which is an oscillation of approximate amplitude 1/4 about a level of 25 oz.

6.(a) Using the Principle of Conservation of Energy, the speed v of a particle falling from a height h is given by

$$\frac{1}{2}mv^2 = mgh\,.$$

(b) The outflow rate is (outflow cross-section area)×(outflow velocity):

$$\alpha\, a\sqrt{2gh}$$

At any instant, the volume of water in the tank is

$$V(h) = \int_0^h A(u)du \,.$$

The time rate of change of the volume is given by

$$\frac{dV}{dt} = \frac{dV}{dh}\frac{dh}{dt} = A(h)\,\frac{dh}{dt}.$$

Since the volume is decreasing,

$$\frac{dV}{dt} = -\alpha\, a\sqrt{2gh} \,.$$

(c) With $A(h) = \pi$, $a = 0.01\,\pi$, $\alpha = 0.6$, the ODE for the water level h is

$$\pi\,\frac{dh}{dt} = -0.006\,\pi\sqrt{2gh} \,,$$

with solution

$$h(t) = 0.000018\,g\,t^2 - 0.006\,\sqrt{2gh(0)}\;\,t + h(0) \,.$$

Setting $h(0) = 3$ and $g = 9.8$,

$$h(t) = 0.0001764\; t^2 - 0.046\; t + 3$$

resulting in $h(t) = 0$ for $t \approx 130.4$ s.

7.(a) The equation governing the value of the investment is $dS/dt = r\,S$. The value of the investment, at any time, is given by $S(t) = S_0 e^{rt}$. Setting $S(T) = 2S_0$, the required time is $T = \ln(2)/r$.

(b) For the case $r = .07$, $T \approx 9.9$ yr.

(c) Referring to part (a), $r = \ln(2)/T$. Setting $T = 8$, the required interest rate is to be approximately $r = 8.66$.

12.(a) Let $Q' = -r\,Q$. The general solution is $Q(t) = Q_0 e^{-rt}$. Based on the definition of half-life, consider the equation $Q_0/2 = Q_0 e^{-5730\,r}$. It follows that $-5730\,r = \ln(1/2)$, that is, $r = 1.2097 \times 10^{-4}$ per year.

(b) The amount of carbon-14 is given by $Q(t) = Q_0\, e^{-1.2097\times 10^{-4} t}$.

(c) Given that $Q(T) = Q_0/5$, we have the equation $1/5 = e^{-1.2097\times 10^{-4} T}$. Solving for the decay time, the apparent age of the remains is approximately $T = 13,305$ years.

13. Let $P(t)$ be the population size of mosquitoes at any time t. The rate of increase of the mosquito population is rP. The population decreases by $20,000$ per day. Hence the equation that models the population is given by

$$dP/dt = rP - 20,000.$$

Note that the variable t represents days. The solution is

$$P(t) = P_0 e^{rt} - \frac{20,000}{r}(e^{rt} - 1).$$

In the absence of predators, the governing equation is $dP_1/dt = rP_1$, with solution $P_1(t) = P_0 e^{rt}$. Based on the data, set $P_1(7) = 2P_0$, that is, $2P_0 = P_0 e^{7r}$. The growth rate is determined as $r = \ln(2)/7 = .09902$ per day. Therefore the population, including the predation by birds, is

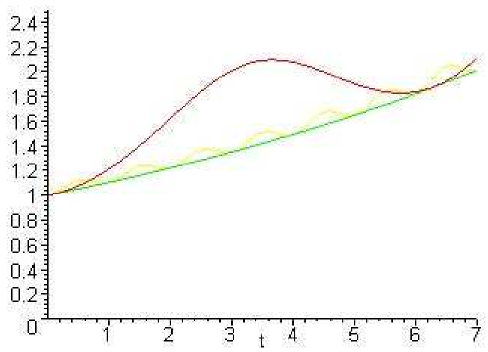
$$P(t) = 2 \times 10^5 e^{.099t} - 201,997(e^{.099t} - 1) = 201,997.3 - 1977.3\, e^{.099t}.$$

14.(a) $y(t) = e^{2/10 + t/10 - 2\cos t/10}$. The (first) doubling time is $\tau \approx 2.9632$.

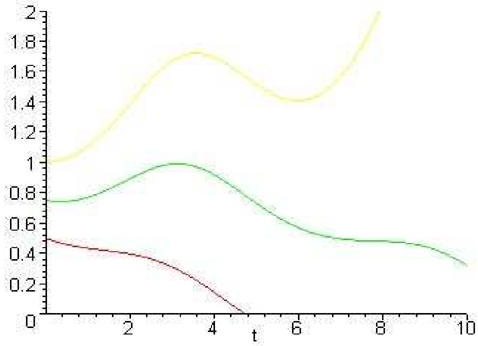
(b) The differential equation is $dy/dt = y/10$, with solution $y(t) = y(0)e^{t/10}$. The doubling time is given by $\tau = 10 \ln 2 \approx 6.9315$.

(c) Consider the differential equation $dy/dt = (0.5 + \sin(2\pi t))\, y/5$. The equation is separable, with $\frac{1}{y}dy = (0.1 + \frac{1}{5}\sin(2\pi t))dt$. Integrating both sides, with respect to the appropriate variable, we obtain $\ln y = (\pi t - \cos(2\pi t))/10\pi + c$. Invoking the initial condition, the solution is $y(t) = e^{(1 + \pi t - \cos(2\pi t))/10\pi}$. The doubling-time is $\tau \approx 6.3804$. The doubling time approaches the value found in part (b).

(d)



15.(a) The differential equation $dy/dt = r(t)\, y - k$ is linear, with integrating factor $\mu(t) = e^{-\int r(t)dt}$. Write the equation as $(\mu\, y)' = -k\, \mu(t)$. Integration of both sides yields the general solution $y = \left[-k \int \mu(\tau)d\tau + y_0\, \mu(0)\right]/\mu(t)$. In this problem, the integrating factor is $\mu(t) = e^{(\cos\, t - t)/5}$.



(b) The population becomes extinct, if $y(t^*) = 0$, for some $t = t^*$. Referring to part (a), we find that $y(t^*) = 0$ when

$$\int_0^{t^*} e^{(\cos\,\tau - \tau)/5} d\tau = 5\, e^{1/5} y_c.$$

It can be shown that the integral on the left hand side increases monotonically, from zero to a limiting value of approximately 5.0893. Hence extinction can happen only if $5\, e^{1/5} y_c < 5.0893$, that is, $y_c < 0.8333$.

(c) Repeating the argument in part (b), it follows that $y(t^*) = 0$ when

$$\int_0^{t^*} e^{(\cos\,\tau - \tau)/5} d\tau = \frac{1}{k}\, e^{1/5} y_c.$$

Hence extinction can happen only if $e^{1/5} y_c / k < 5.0893$, that is, $y_c < 4.1667\, k$.

(d) Evidently, y_c is a linear function of the parameter k.

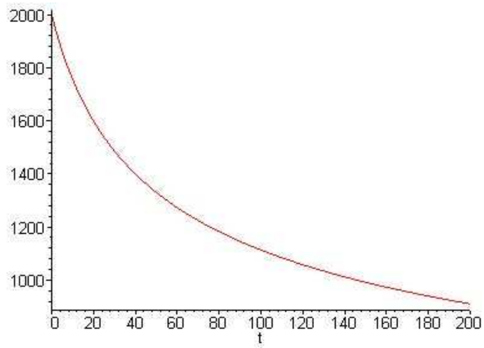
17.(a) The solution of the governing equation satisfies

$$u^3 = \frac{u_0^3}{3\,\alpha\, u_0^3\, t + 1}\,.$$

With the given data, it follows that

$$u(t) = \frac{2000}{\sqrt[3]{6\,t/125 + 1}}\,.$$

(b)



(c) Numerical evaluation results in $u(t) = 600$ for $t \approx 750.77$ s.

19.(a) The concentration is $c(t) = k + P/r + (c_0 - k - P/r)e^{-rt/V}$. It is easy to see that $\lim_{t\to\infty} c(t) = k + P/r$.

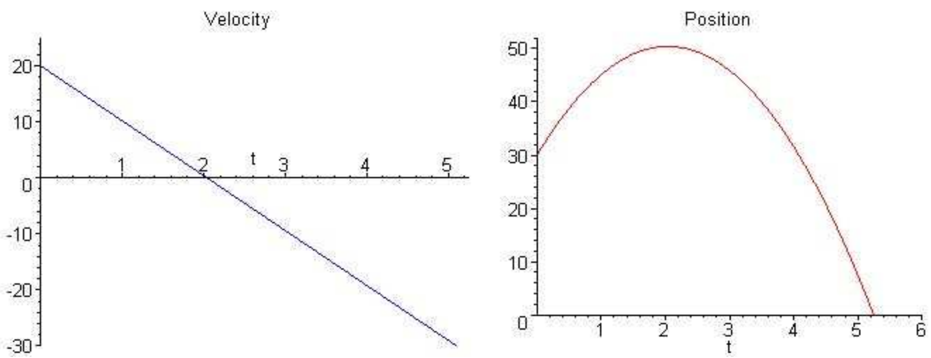
(b) $c(t) = c_0\, e^{-rt/V}$. The reduction times are $T_{50} = V \ln 2/r$ and $T_{10} = V \ln 10/r$.

(c) The reduction times are

$$T_S = (65.2)\ln 10/12{,}200 = 430.85 \text{ years}; T_M = (158)\ln 10/4{,}900 = 71.4 \text{ years};$$

$$T_E = (175)\ln 10/460 = 6.05 \text{ years}; T_O = (209)\ln 10/16{,}000 = 17.63 \text{ years}.$$

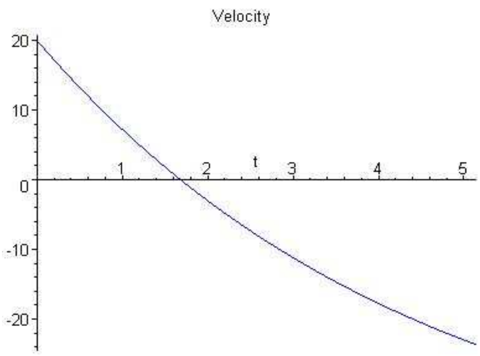
20.(c)

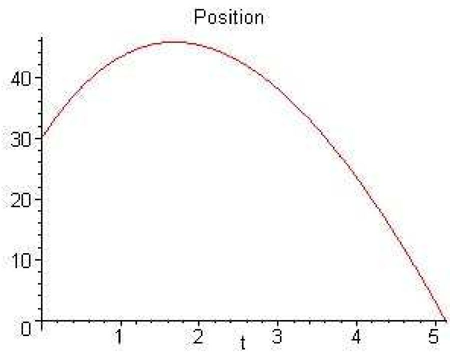


21.(a) The differential equation for the motion is $m\, dv/dt = -v/30 - mg$. Given the initial condition $v(0) = 20$ m/s , the solution is $v(t) = -44.1 + 64.1\, e^{-t/4.5}$. Setting $v(t_1) = 0$, the ball reaches the maximum height at $t_1 = 1.683$ s. Integrating $v(t)$, the position is given by $x(t) = 318.45 - 44.1\, t - 288.45\, e^{-t/4.5}$. Hence the maximum height is $x(t_1) = 45.78$ m.

(b) Setting $x(t_2) = 0$, the ball hits the ground at $t_2 = 5.128$ s.

(c)





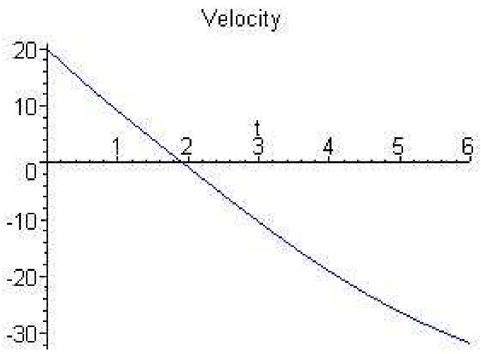
22.(a) The differential equation for the upward motion is $mdv/dt = -\mu v^2 - mg$, in which $\mu = 1/1325$. This equation is separable, with $\frac{m}{\mu\, v^2 + mg}dv = -dt$. Integrating both sides and invoking the initial condition, $v(t) = 44.133\ \tan(.425 - .222\, t)$. Setting $v(t_1) = 0$, the ball reaches the maximum height at $t_1 = 1.916$ s . Integrating $v(t)$, the position is given by $x(t) = 198.75\ \ln\left[\cos(0.222\, t - 0.425)\right] + 48.57$. Therefore the maximum height is $x(t_1) = 48.56$ m .

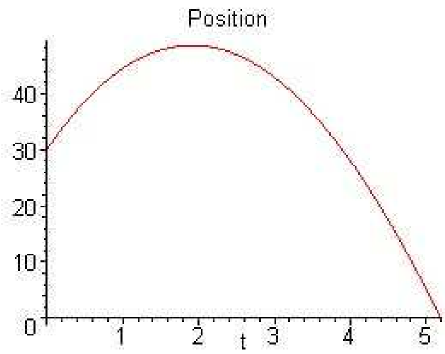
(b) The differential equation for the downward motion is $m\, dv/dt = +\mu v^2 - mg$. This equation is also separable, with $\frac{m}{mg - \mu\, v^2}dv = -dt$. For convenience, set $t = 0$ at the top of the trajectory. The new initial condition becomes $v(0) = 0$. Integrating both sides and invoking the initial condition, we obtain

$$\ln((44.13 - v)/(44.13 + v)) = t/2.25.$$

Solving for the velocity, $v(t) = 44.13(1 - e^{t/2.25})/(1 + e^{t/2.25})$. Integrating $v(t)$, the position is given by $x(t) = 99.29\ln(e^{t/2.25}/(1 + e^{t/2.25})^2) + 186.2$. To estimate the duration of the downward motion, set $x(t_2) = 0$, resulting in $t_2 = 3.276$ s. Hence the total time that the ball remains in the air is $t_1 + t_2 = 5.192$ s.

(c)





23.(a) Measure the positive direction of motion downward. Based on Newton's second law, the equation of motion is given by

$$m\frac{dv}{dt} = \begin{cases} -0.75\,v + mg, & 0 < t < 10 \\ -12\,v + mg, & t > 10 \end{cases}.$$

Note that gravity acts in the positive direction, and the drag force is resistive. During the first ten seconds of fall, the initial value problem is $dv/dt = -v/7.5 + 32$, with initial velocity $v(0) = 0$ ft/s. This differential equation is separable and linear, with solution $v(t) = 240(1 - e^{-t/7.5})$. Hence $v(10) = 176.7$ ft/s.

(b) Integrating the velocity, with $x(t) = 0$, the distance fallen is given by

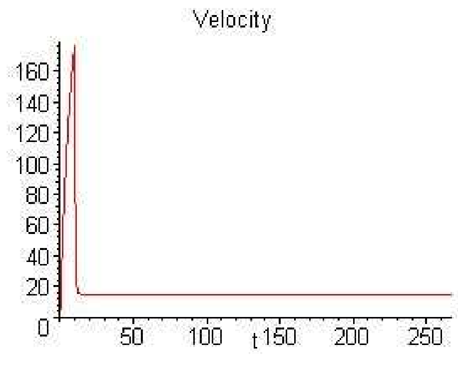
$$x(t) = 240\,t + 1800\,e^{-t/7.5} - 1800\,.$$

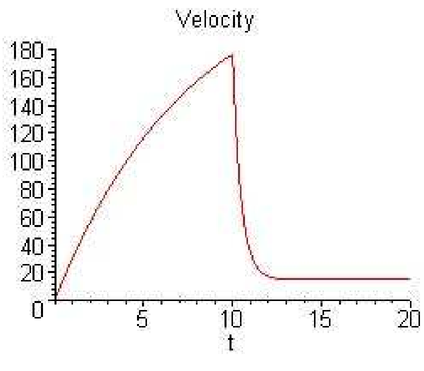
Hence $x(10) = 1074.5$ ft.

(c) For computational purposes, reset time to $t = 0$. For the remainder of the motion, the initial value problem is $dv/dt = -32v/15 + 32$, with specified initial velocity $v(0) = 176.7$ ft/s. The solution is given by $v(t) = 15 + 161.7e^{-32\,t/15}$. As $t \to \infty$, $v(t) \to v_L = 15$ ft/s.

(d) Integrating the velocity, with $x(0) = 1074.5$, the distance fallen after the parachute is open is given by $x(t) = 15t - 75.8e^{-32t/15} + 1150.3$. To find the duration of the second part of the motion, estimate the root of the transcendental equation $15T - 75.8e^{-32T/15} + 1150.3 = 5000$. The result is $T = 256.6$ s.

(e)





24.(a) Setting $-\mu v^2 = v(dv/dx)$, we obtain

$$\frac{dv}{dx} = -\mu v.$$

(b) The speed v of the sled satisfies

$$\ln(\frac{v}{v_0}) = -\mu x.$$

Noting that the unit conversion factors cancel, solution of

$$\ln(\frac{15}{150}) = -2000\,\mu$$

results in $\mu = \ln(10)/2000\ \text{ft}^{-1} \approx 0.00115\ \text{ft}^{-1} \approx 6.0788\ \text{mi}^{-1}$.

(c) Solution of

$$\frac{dv}{dt} = -\mu v^2$$

can be expressed as

$$\frac{1}{v} - \frac{1}{v_0} = \mu t.$$

Noting that $1\,\text{mi/hr} \approx 1.467\,\text{ft/s}$, the elapsed time is

$$t = \frac{\frac{1}{15} - \frac{1}{150}}{(1.467)(0.00115)} \approx 35.56\ \text{s}.$$

25.(a) Measure the positive direction of motion upward. The equation of motion is given by $mdv/dt = -k\,v - mg$. The initial value problem is $dv/dt = -kv/m - g$, with $v(0) = v_0$. The solution is $v(t) = -mg/k + (v_0 + mg/k)e^{-kt/m}$. Setting $v(t_m) = 0$, the maximum height is reached at time $t_m = (m/k)\ln\left[(mg + k\,v_0)/mg\right]$. Integrating the velocity, the position of the body is

$$x(t) = -mg\,t/k + \left[(\frac{m}{k})^2 g + \frac{m\,v_0}{k}\right](1 - e^{-kt/m}).$$

Hence the maximum height reached is

$$x_m = x(t_m) = \frac{m\,v_0}{k} - g(\frac{m}{k})^2 \ln\left[\frac{mg + k\,v_0}{mg}\right].$$

(b) Recall that for $\delta \ll 1$, $\ln(1+\delta) = \delta - \frac{1}{2}\delta^2 + \frac{1}{3}\delta^3 - \frac{1}{4}\delta^4 + \ldots$

26.(b) Using L'Hospital's rule,

$$\lim_{k \to 0} \frac{-mg + (k\,v_0 + mg)e^{-kt/m}}{k} = \lim_{k \to 0} -\frac{t}{m}(k\,v_0 + mg)e^{-kt/m} = -gt.$$

(c)

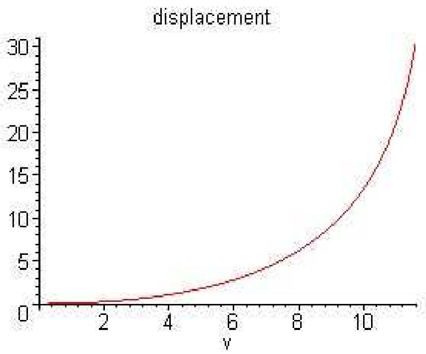
$$\lim_{m \to 0}\left[-\frac{mg}{k} + (\frac{mg}{k} + v_0)e^{-kt/m}\right] = 0,$$

since $\lim_{m \to 0} e^{-kt/m} = 0$.

28.(a) In terms of displacement, the differential equation is $mvdv/dx = -kv + mg$. This follows from the chain rule: $\frac{dv}{dt} = \frac{dv}{dx}\frac{dx}{dt} = v\frac{dv}{dx}$. The differential equation is separable, with

$$x(v) = -\frac{mv}{k} - \frac{m^2 g}{k^2}\ln\left|\frac{mg - k\,v}{mg}\right|.$$

The inverse exists, since both x and v are monotone increasing. In terms of the given parameters, $x(v) = -1.25\,v - 15.31\,\ln|0.0816\,v - 1|$.



(b) $x(10) = 13.45$ meters. The required value is $k = 0.24$.

(c) In part (a), set $v = 10$ m/s and $x = 10$ meters.

29.(a) Let x represent the height above the earth's surface. The equation of motion is given by $m\frac{dv}{dt} = -G\frac{Mm}{(R+x)^2}$, in which G is the universal gravitational constant. The symbols M and R are the mass and radius of the earth, respectively. By the chain rule,

$$mv\frac{dv}{dx} = -G\frac{Mm}{(R+x)^2}.$$

This equation is separable, with $vdv = -GM(R+x)^{-2}dx$. Integrating both sides, and invoking the initial condition $v(0) = \sqrt{2gR}$, the solution is

$$v^2 = 2GM(R+x)^{-1} + 2gR - 2GM/R.$$

From elementary physics, it follows that $g = GM/R^2$. Therefore

$$v(x) = \sqrt{2g}\,(R/\sqrt{R+x}).$$

(Note that $g = 78,545$ mi/hr^2.)

(b) We now consider $dx/dt = \sqrt{2g}\,(R/\sqrt{R+x})$. This equation is also separable, with $\sqrt{R+x}\,dx = \sqrt{2g}\,Rdt$. By definition of the variable x, the initial condition is $x(0) = 0$. Integrating both sides, we obtain

$$x(t) = (\frac{3}{2}(\sqrt{2g}\,R\,t + \frac{2}{3}R^{3/2}))^{2/3} - R.$$

Setting the distance $x(T) + R = 240,000$, and solving for T, the duration of such a flight would be $T \approx 49$ hours.

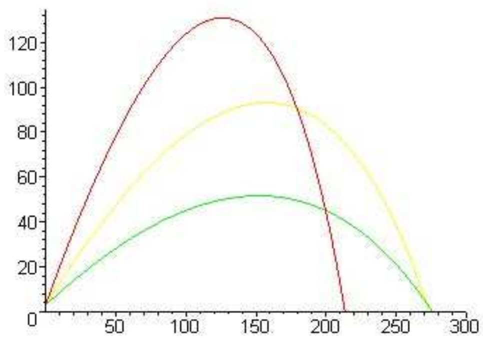
31.(a) Both equations are linear and separable. Initial conditions: $v(0) = u\cos A$ and $w(0) = u\sin A$. The two solutions are

$$v(t) = (u\cos A)e^{-rt} \quad \text{and} \quad w(t) = -g/r + (u\sin A + g/r)e^{-rt}.$$

(b) Integrating the solutions in part (a), and invoking the initial conditions, the coordinates are $x(t) = u\cos A(1 - e^{-rt})/r$ and

$$y(t) = -gt/r + (g + ur\,\sin\,A + hr^2)/r^2 - (\frac{u}{r}\sin\,A + g/r^2)e^{-rt}.$$

(c)



(d) Let T be the time that it takes the ball to go 350 ft horizontally. Then from above, $e^{-T/5} = (u\,\cos\,A - 70)/u\,\cos\,A$. At the same time, the height of the ball is given by

$$y(T) = -160T + 267 + 125u\sin A - \frac{(800 + 5u\sin A)(u\cos A - 70)}{u\cos A}.$$

Hence A and u must satisfy the inequality

$$800\ln\left[\frac{u\,\cos\,A - 70}{u\,\cos\,A}\right] + 267 + 125u\sin\,A -$$

$$-(800 + 5u\,\sin\,A)\,[(u\,\cos\,A - 70)/u\,\cos\,A\,] \geq 10\,.$$

32.(a) Solving equation (i), $y'(x) = \left[(k^2 - y)/y\right]^{1/2}$. The positive answer is chosen, since y is an increasing function of x.

(b) Let $y = k^2\sin^2 t$. Then $dy = 2k^2\sin t\cos t dt$. Substituting into the equation in part (a), we find that

$$\frac{2k^2\sin t\cos t dt}{dx} = \frac{\cos t}{\sin t}.$$

Hence $2k^2\sin^2 t dt = dx$.

(c) Setting $\theta = 2t$, we further obtain $k^2\sin^2\frac{\theta}{2}\,d\theta = dx$. Integrating both sides of the equation and noting that $t = \theta = 0$ corresponds to the origin, we obtain the solutions

$$x(\theta) = k^2(\theta - \sin\theta)/2 \quad \text{and [from part (b)]} \quad y(\theta) = k^2(1 - \cos\theta)/2.$$

(d) Note that $y/x = (1 - \cos\theta)/(\theta - \sin\theta)$. Setting $x = 1$, $y = 2$, the solution of the equation $(1 - \cos\theta)/(\theta - \sin\theta) = 2$ is $\theta \approx 1.401$. Substitution into either of the expressions yields $k \approx 2.193$.

2.4

2. Rewrite the differential equation as

$$y' + \frac{1}{t(t-4)}\,y = 0\,.$$

It is evident that the coefficient $1/t(t-4)$ is continuous everywhere except at $t = 0\,,4$. Since the initial condition is specified at $t = 2$, Theorem 2.4.1 assures the existence of a unique solution on the interval $0 < t < 4$.

3. The function $\tan t$ is discontinuous at odd multiples of $\frac{\pi}{2}$. Since $\frac{\pi}{2} < \pi < \frac{3\pi}{2}$, the initial value problem has a unique solution on the interval $(\frac{\pi}{2}\,, \frac{3\pi}{2})$.

5. $p(t) = 2t/(4 - t^2)$ and $g(t) = 3t^2/(4 - t^2)$. These functions are discontinuous at $x = \pm 2$. The initial value problem has a unique solution on the interval $(-2\,, 2)$.

6. The function $\ln t$ is defined and continuous on the interval $(0\,,\infty)$. At $t = 1$, $\ln t = 0$, so the normal form of the differential equation has a singularity there. Also, $\cot t$ is not defined at integer multiples of π, so the initial value problem will have a solution on the interval $(1, \pi)$.

7. The function $f(t\,,y)$ is continuous everywhere on the plane, except along the straight line $y = -2t/5$. The partial derivative $\partial f/\partial y = -7t/(2t + 5y)^2$ has the same region of continuity.

9. The function $f(t\,,y)$ is discontinuous along the coordinate axes, and on the hyperbola $t^2 - y^2 = 1$. Furthermore,

$$\frac{\partial f}{\partial y} = \frac{\pm 1}{y(1 - t^2 + y^2)} - 2\frac{y\,\ln|ty|}{(1 - t^2 + y^2)^2}$$

has the same points of discontinuity.

10. $f(t\,,y)$ is continuous everywhere on the plane. The partial derivative $\partial f/\partial y$ is also continuous everywhere.

12. The function $f(t\,,y)$ is discontinuous along the lines $t = \pm k\,\pi$ and $y = -1$. The partial derivative $\partial f/\partial y = \cot(t)/(1 + y)^2$ has the same region of continuity.

14. The equation is separable, with $dy/y^2 = 2t\,dt$. Integrating both sides, the solution is given by $y(t) = y_0/(1 - y_0 t^2)$. For $y_0 > 0$, solutions exist as long as $t^2 < 1/y_0$. For $y_0 \le 0$, solutions are defined for all t.

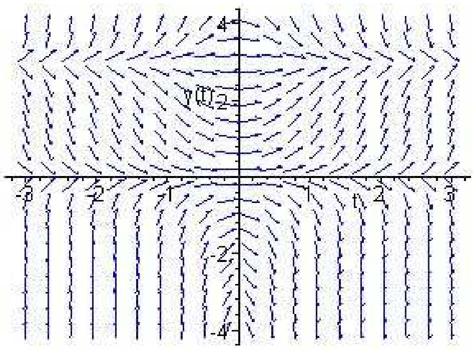
15. The equation is separable, with $dy/y^3 = -\,dt$. Integrating both sides and invoking the initial condition, $y(t) = y_0/\sqrt{2y_0^2 t + 1}$. Solutions exist as long as $2y_0^2 t + 1 > 0$, that is, $2y_0^2 t > -1$. If $y_0 \neq 0$, solutions exist for $t > -1/2y_0^2$. If $y_0 = 0$, then the solution $y(t) = 0$ exists for all t.

16. The function $f(t\,,y)$ is discontinuous along the straight lines $t = -1$ and $y = 0$. The partial derivative $\partial f/\partial y$ is discontinuous along the same lines. The equation is separable, with $y\,dy = t^2\,dt/(1+t^3)$. Integrating and invoking the initial condition, the solution is $y(t) = \left[\frac{2}{3}\ln\left|1+t^3\right| + y_0^2\right]^{1/2}$. Solutions exist as long as

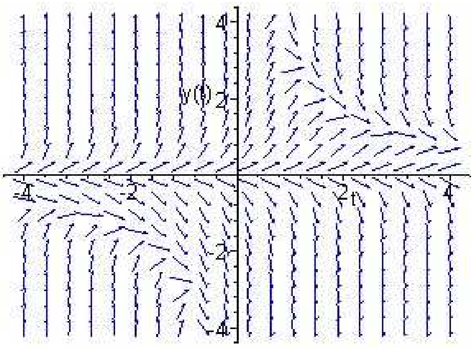
$$\frac{2}{3}\ln\left|1+t^3\right| + y_0^2 \geq 0\,,$$

that is, $y_0^2 \geq -\frac{2}{3}\ln\left|1+t^3\right|$. For all y_0 (it can be verified that $y_0 = 0$ yields a valid solution, even though Theorem 2.4.2 does not guarantee one), solutions exists as long as $\left|1+t^3\right| \geq e^{-3y_0^2/2}$. From above, we must have $t > -1$. Hence the inequality may be written as $t^3 \geq e^{-3y_0^2/2} - 1$. It follows that the solutions are valid for $\left[e^{-3y_0^2/2} - 1\right]^{1/3} < t < \infty$.

17.

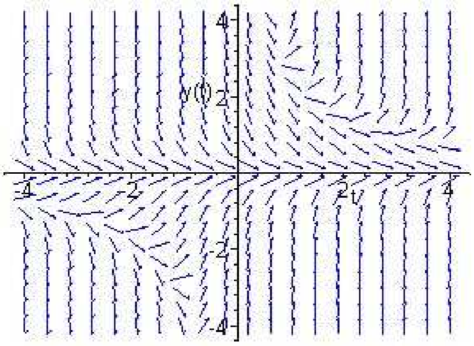


18.



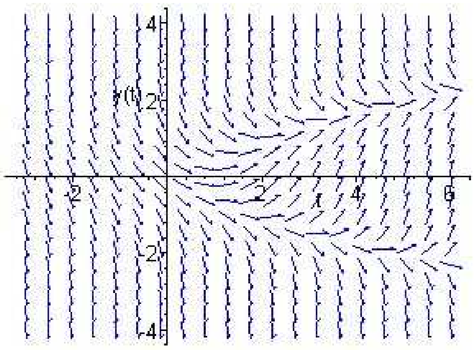
Based on the direction field, and the differential equation, for $y_0 < 0$, the slopes eventually become negative, and hence solutions tend to $-\infty$. For $y_0 > 0$, solutions increase without bound if $t_0 < 0$. Otherwise, the slopes eventually become negative, and solutions tend to zero. Furthermore, $y_0 = 0$ is an equilibrium solution. Note that slopes are zero along the curves $y = 0$ and $ty = 3$.

19.



For initial conditions (t_0, y_0) satisfying $ty < 3$, the respective solutions all tend to zero. Solutions with initial conditions above or below the hyperbola $ty = 3$ eventually tend to $\pm\infty$. Also, $y_0 = 0$ is an equilibrium solution.

20.



Solutions with $t_0 < 0$ all tend to $-\infty$. Solutions with initial conditions (t_0, y_0) to the right of the parabola $t = 1 + y^2$ asymptotically approach the parabola as $t \to \infty$. Integral curves with initial conditions above the parabola (and $y_0 > 0$) also approach the curve. The slopes for solutions with initial conditions below the parabola (and $y_0 < 0$) are all negative. These solutions tend to $-\infty$.

21. Define $y_c(t) = \frac{2}{3}(t-c)^{3/2}u(t-c)$, in which $u(t)$ is the Heaviside step function. Note that $y_c(c) = y_c(0) = 0$ and $y_c(c + (3/2)^{2/3}) = 1$.

(a) Let $c = 1 - (3/2)^{2/3}$.

(b) Let $c = 2 - (3/2)^{2/3}$.

(c) Observe that $y_0(2) = \frac{2}{3}(2)^{3/2}$, $y_c(t) < \frac{2}{3}(2)^{3/2}$ for $0 < c < 2$, and that $y_c(2) = 0$ for $c \geq 2$. So for any $c \geq 0$, $\pm y_c(2) \in [-2, 2]$.

26.(a) Recalling Eq.(33) in Section 2.1,

$$y = \frac{1}{\mu(t)} \int_{t_0}^{t} \mu(s)g(s)\, ds + \frac{c}{\mu(t)}.$$

It is evident that $y_1(t) = \frac{1}{\mu(t)}$ and $y_2(t) = \frac{1}{\mu(t)} \int_{t_0}^{t} \mu(s)g(s)\, ds$.

(b) By definition, $\frac{1}{\mu(t)} = e^{-\int p(t)dt}$. Hence $y_1' = -p(t)/\mu(t) = -p(t)y_1$. That is, $y_1' + p(t)y_1 = 0$.

(c) $y_2' = (-p(t)/\mu(t)) \int_0^t \mu(s)g(s)\, ds + \mu(t)g(t)/\mu(t) = -p(t)y_2 + g(t)$. This implies that $y_2' + p(t)y_2 = g(t)$.

30. Since $n = 3$, set $v = y^{-2}$. It follows that $\frac{dv}{dt} = -2y^{-3}\frac{dy}{dt}$ and $\frac{dy}{dt} = -\frac{y^3}{2}\frac{dv}{dt}$. Substitution into the differential equation yields $-\frac{y^3}{2}\frac{dv}{dt} - \varepsilon y = -\sigma y^3$, which further results in $v' + 2\varepsilon v = 2\sigma$. The latter differential equation is linear, and can be written as $(ve^{2\varepsilon t})' = 2\sigma e^{2\varepsilon t}$. The solution is given by $v(t) = \sigma/\varepsilon + ce^{-2\varepsilon t}$. Converting back to the original dependent variable, $y = \pm v^{-1/2}$.

31. Since $n = 3$, set $v = y^{-2}$. It follows that $\frac{dv}{dt} = -2y^{-3}\frac{dy}{dt}$ and $\frac{dy}{dt} = -\frac{y^3}{2}\frac{dv}{dt}$. The differential equation is written as $-\frac{y^3}{2}\frac{dv}{dt} - (\Gamma \cos t + T)y = \sigma y^3$, which upon further substitution is $v' + 2(\Gamma \cos t + T)v = 2$. This ODE is linear, with integrating factor $\mu(t) = e^{2\int(\Gamma \cos t + T)dt} = e^{2\Gamma \sin t + 2Tt}$. The solution is

$$v(t) = 2e^{-(2\Gamma \sin t + 2Tt)} \int_0^t e^{2\Gamma \sin \tau + 2T\tau} d\tau + ce^{-(2\Gamma \sin t + 2Tt)}.$$

Converting back to the original dependent variable, $y = \pm v^{-1/2}$.

33. The solution of the initial value problem $y_1' + 2y_1 = 0$, $y_1(0) = 1$ is $y_1(t) = e^{-2t}$. Therefore $y(1^-) = y_1(1) = e^{-2}$. On the interval $(1, \infty)$, the differential equation is $y_2' + y_2 = 0$, with $y_2(t) = ce^{-t}$. Therefore $y(1^+) = y_2(1) = ce^{-1}$. Equating the limits $y(1^-) = y(1^+)$, we require that $c = e^{-1}$. Hence the global solution of the initial value problem is

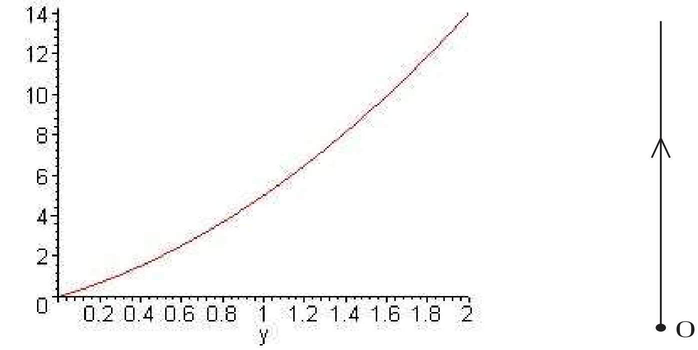
$$y(t) = \begin{cases} e^{-2t}, & 0 \le t \le 1 \\ e^{-1-t}, & t > 1 \end{cases}.$$

Note the discontinuity of the derivative

$$y'(t) = \begin{cases} -2e^{-2t}, & 0 < t < 1 \\ -e^{-1-t}, & t > 1 \end{cases}.$$

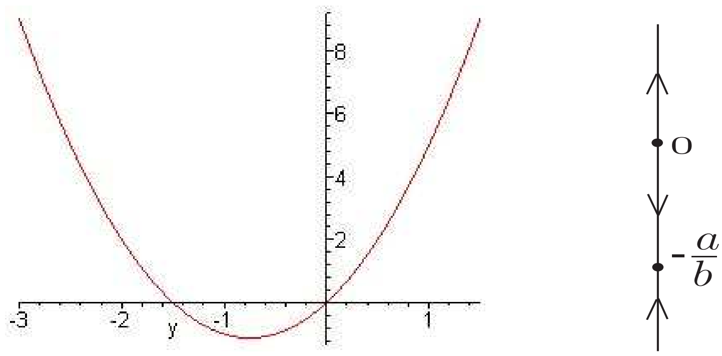
2.5

1.



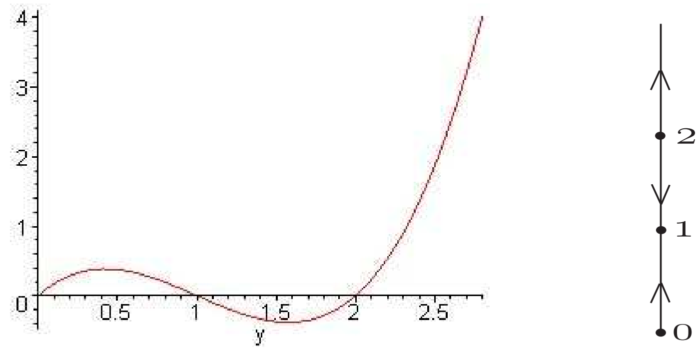
For $y_0 \geq 0$, the only equilibrium point is $y^* = 0$, and $f'(0) = a > 0$, hence the equilibrium solution $y = 0$ is unstable.

2.



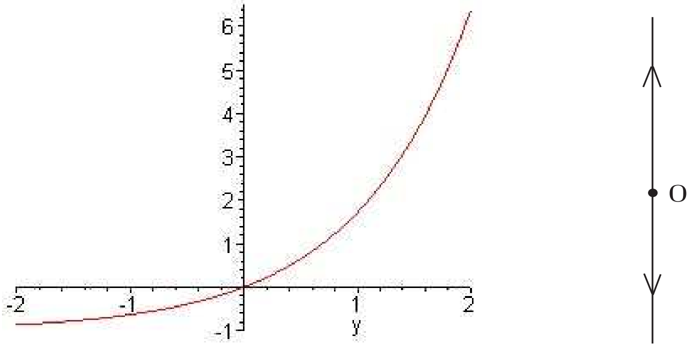
The equilibrium points are $y^* = -a/b$ and $y^* = 0$, and $f'(-a/b) < 0$, therefore the equilibrium solution $y = -a/b$ is asymptotically stable; $f'(0) > 0$, therefore the equilibrium solution $y = 0$ is unstable.

3.



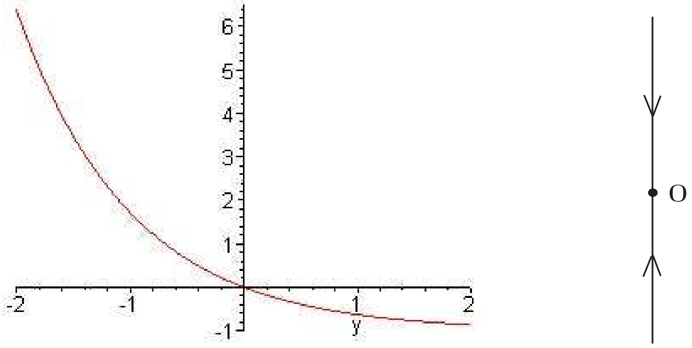
The equilibrium solutions $y = 0$ and $y = 2$ are unstable, the equilibrium solution $y = 1$ is asymptotically stable.

4.



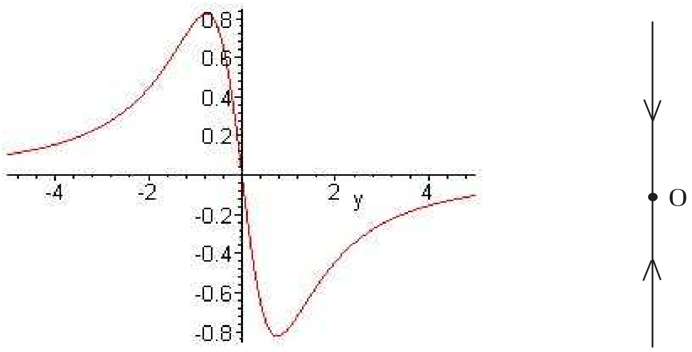
The only equilibrium point is $y^* = 0$, and $f'(0) > 0$, hence the equilibrium solution $y = 0$ is unstable.

5.



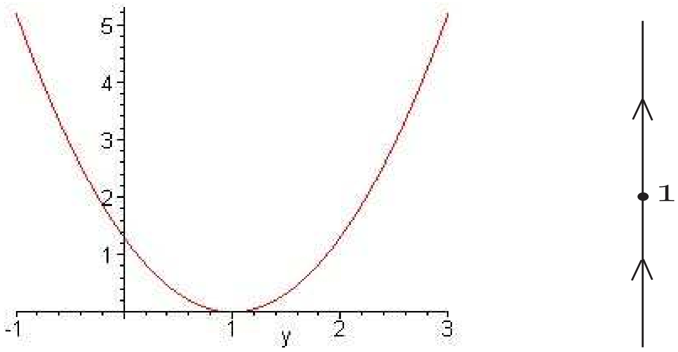
The only equilibrium point is $y^* = 0$, and $f'(0) < 0$, hence the equilibrium solution $y = 0$ is asymptotically stable.

6.

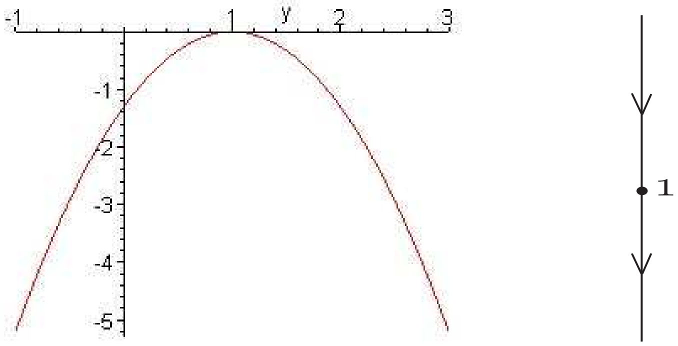


The equilibrium solution $y = 0$ is asymptotically stable.

7.(b)

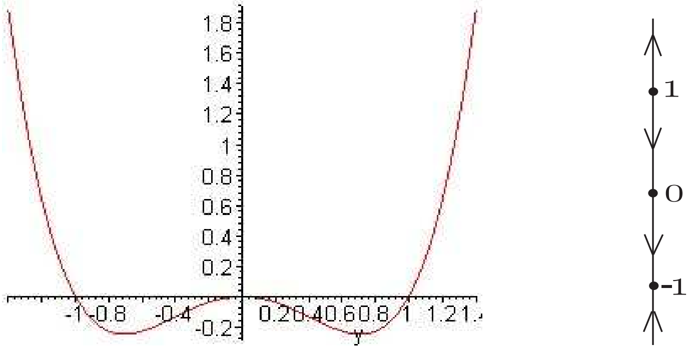


8.



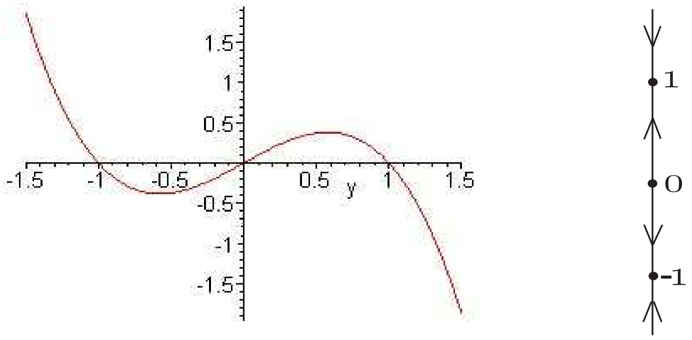
The only equilibrium point is $y^* = 1$, and $f'(1) = 0$, also, $y' < 0$ for $y \neq 1$. As long as $y_0 \neq 1$, the corresponding solution is monotone decreasing. Hence the equilibrium solution $y = 1$ is semistable.

9.



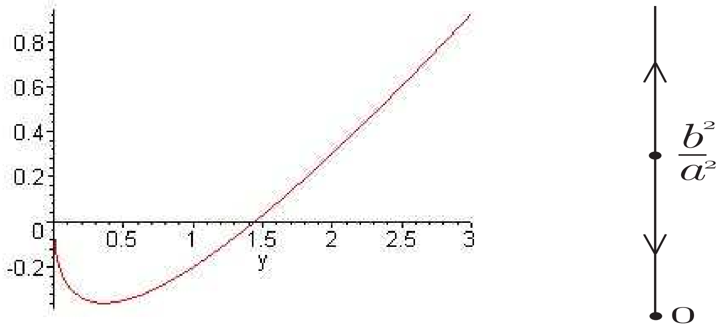
The equilibrium solution $y = -1$ is asymptotically stable, $y = 0$ is semistable and $y = 1$ is unstable.

10.



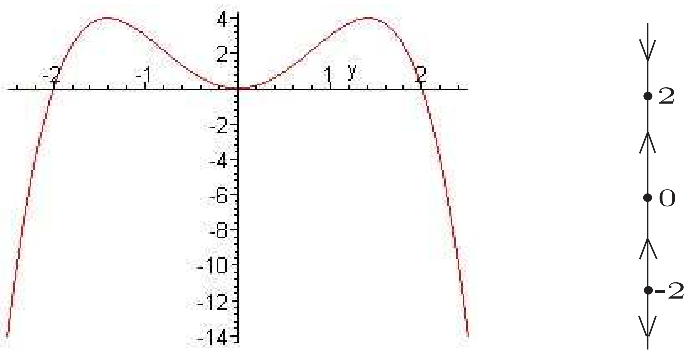
The equilibrium points are $y^* = 0, \pm 1$, and $f'(y) = 1 - 3y^2$. The equilibrium solution $y = 0$ is unstable, and the remaining two are asymptotically stable.

11.



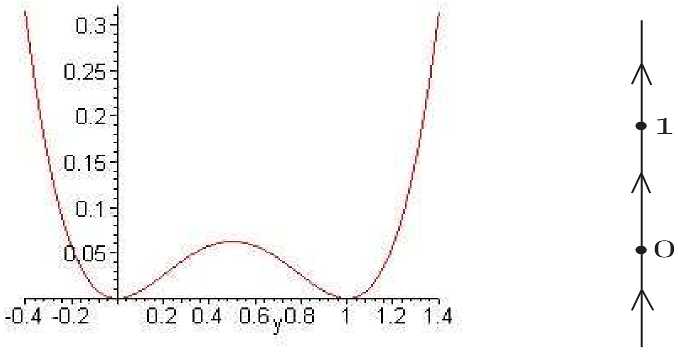
The equilibrium solution $y = 0$ is asymptotically stable, the equilibrium solution $y = b^2/a^2$ is unstable.

12.



The equilibrium points are $y^* = 0, \pm 2$, and $f'(y) = 8y - 4y^3$. The equilibrium solutions $y = -2$ and $y = 2$ are unstable and asymptotically stable, respectively. The equilibrium solution $y = 0$ is semistable.

13.



The equilibrium points are $y^* = 0,\ 1$. $f'(y) = 2y - 6y^2 + 4y^3$. Both equilibrium solutions are semistable.

15.(a) Inverting Eq.(11), Eq.(13) shows t as a function of the population y and the carrying capacity K. With $y_0 = K/3$,

$$t = -\frac{1}{r}\ln\left|\frac{(1/3)\,[1-(y/K)]}{(y/K)\,[1-(1/3)]}\right|.$$

Setting $y = 2y_0$,

$$\tau = -\frac{1}{r}\ln\left|\frac{(1/3)\,[1-(2/3)]}{(2/3)\,[1-(1/3)]}\right|.$$

That is, $\tau = (\ln 4)/r$. If $r = 0.025$ per year, $\tau \approx 55.45$ years.

(b) In Eq.(13), set $y_0/K = \alpha$ and $y/K = \beta$. As a result, we obtain

$$T = -\frac{1}{r}\ln\left|\frac{\alpha\,[1-\beta]}{\beta\,[1-\alpha]}\right|.$$

Given $\alpha = 0.1$, $\beta = 0.9$ and $r = 0.025$ per year, $\tau \approx 175.78$ years.

17.(a) Consider the change of variable $u = \ln(y/K)$. Differentiating both sides with respect to t, $u' = y'/y$. Substitution into the Gompertz equation yields $u' = -ru$, with solution $u = u_0e^{-rt}$. It follows that $\ln(y/K) = \ln(y_0/K)e^{-rt}$. That is,

$$\frac{y}{K} = e^{\ln(y_0/K)e^{-rt}}.$$

(b) Given $K = 80.5 \times 10^6$, $y_0/K = 0.25$ and $r = 0.71$ per year, $y(2) = 57.58 \times 10^6$.

(c) Solving for t,

$$t = -\frac{1}{r}\ln\left[\frac{\ln(y/K)}{\ln(y_0/K)}\right].$$

Setting $y(\tau) = 0.75K$, the corresponding time is $\tau \approx 2.21$ years.

19.(a) The rate of increase of the volume is given by rate of flow in$-$rate of flow out. That is, $dV/dt = k - \alpha a\sqrt{2gh}$. Since the cross section is constant, $dV/dt = Adh/dt$. Hence the governing equation is $dh/dt = (k - \alpha a\sqrt{2gh})/A$.

(b) Setting $dh/dt = 0$, the equilibrium height is $h_e = \frac{1}{2g}(\frac{k}{\alpha a})^2$. Furthermore, since $f'(h_e) < 0$, it follows that the equilibrium height is asymptotically stable.

22.(a) The equilibrium points are at $y^* = 0$ and $y^* = 1$. Since $f'(y) = \alpha - 2\alpha y$, the equilibrium solution $y = 0$ is unstable and the equilibrium solution $y = 1$ is asymptotically stable.

(b) The ODE is separable, with $[y(1-y)]^{-1}\,dy = \alpha\,dt$. Integrating both sides and invoking the initial condition, the solution is

$$y(t) = \frac{y_0\,e^{\alpha t}}{1 - y_0 + y_0\,e^{\alpha t}}\,.$$

It is evident that (independent of y_0) $\lim_{t\to-\infty} y(t) = 0$ and $\lim_{t\to\infty} y(t) = 1$.

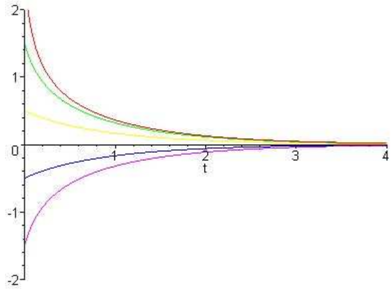
23.(a) $y(t) = y_0\,e^{-\beta t}$.

(b) From part (a), $dx/dt = -\alpha x y_0 e^{-\beta t}$. Separating variables, $dx/x = -\alpha y_0 e^{-\beta t}dt$. Integrating both sides, the solution is $x(t) = x_0\,e^{-\alpha\,y_0(1-e^{-\beta t})/\beta}$.

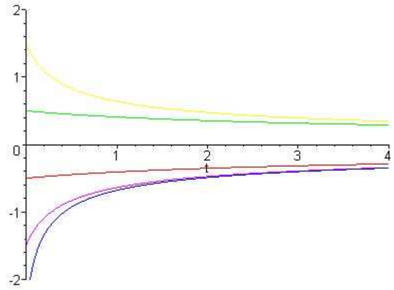
(c) As $t \to \infty$, $y(t) \to 0$ and $x(t) \to x_0\,e^{-\alpha\,y_0/\beta}$. Over a long period of time, the proportion of carriers vanishes. Therefore the proportion of the population that escapes the epidemic is the proportion of susceptibles left at that time, $x_0\,e^{-\alpha\,y_0/\beta}$.

26.(a) For $a < 0$, the only critical point is at $y = 0$, which is asymptotically stable. For $a = 0$, the only critical point is at $y = 0$, which is asymptotically stable. For $a > 0$, the three critical points are at $y = 0$, $\pm\sqrt{a}$. The critical point at $y = 0$ is unstable, whereas the other two are asymptotically stable.

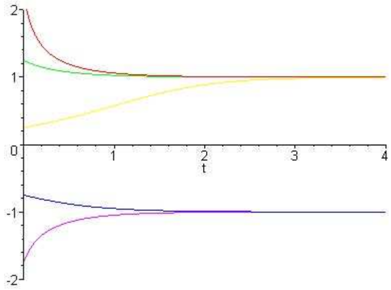
(b)



(a) $a = -1$

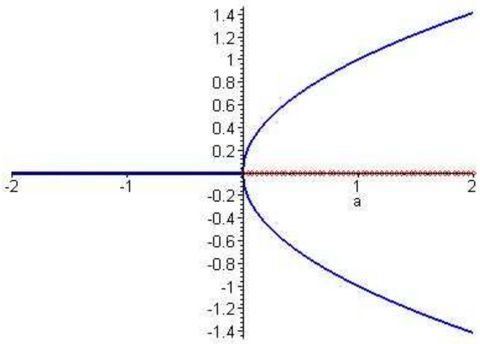


(b) $a = 0$



(c) $a = 1$

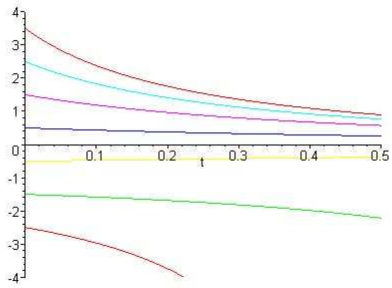
(c)



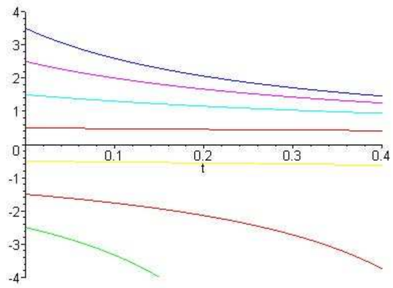
27. $f(y) = y(a - y)$; $f'(y) = a - 2y$.

(a) For $a < 0$, the critical points are at $y = a$ and $y = 0$. Observe that $f'(a) > 0$ and $f'(0) < 0$. Hence $y = a$ is unstable and $y = 0$ asymptotically stable. For $a = 0$, the only critical point is at $y = 0$, which is semistable since $f(y) = -y^2$ is concave down. For $a > 0$, the critical points are at $y = 0$ and $y = a$. Observe that $f'(0) > 0$ and $f'(a) < 0$. Hence $y = 0$ is unstable and $y = a$ asymptotically stable.

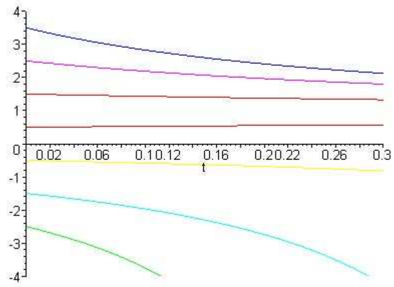
(b)



(a) $a = -1$

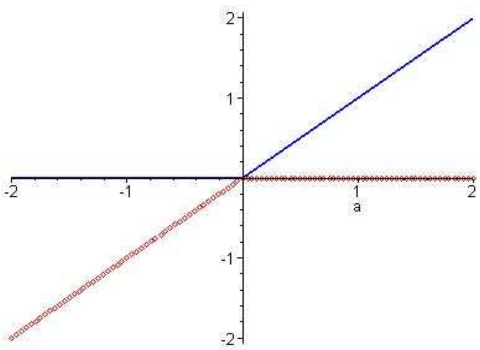


(b) $a = 0$



(c) $a = 1$

(c)



2.6

1. $M(x,y) = 2x+3$ and $N(x,y) = 2y-2$. Since $M_y = N_x = 0$, the equation is exact. Integrating M with respect to x, while holding y constant, yields $\psi(x,y) = x^2+3x+h(y)$. Now $\psi_y = h'(y)$, and equating with N results in the possible function $h(y) = y^2-2y$. Hence $\psi(x,y) = x^2+3x+y^2-2y$, and the solution is defined implicitly as $x^2+3x+y^2-2y = c$.

2. $M(x,y) = 2x+4y$ and $N(x,y) = 2x-2y$. Note that $M_y \neq N_x$, and hence the differential equation is not exact.

4. First divide both sides by $(2xy+2)$. We now have $M(x,y) = y$ and $N(x,y) = x$. Since $M_y = N_x = 0$, the resulting equation is exact. Integrating M with respect to x, while holding y constant, results in $\psi(x,y) = xy+h(y)$. Differentiating with respect to y, $\psi_y = x+h'(y)$. Setting $\psi_y = N$, we find that $h'(y) = 0$, and hence $h(y) = 0$ is acceptable. Therefore the solution is defined implicitly as $xy = c$. Note that if $xy+1 = 0$, the equation is trivially satisfied.

6. Write the given equation as $(ax-by)dx+(bx-cy)dy$. Now $M(x,y) = ax-by$ and $N(x,y) = bx-cy$. Since $M_y \neq N_x$, the differential equation is not exact.

8. $M(x,y) = e^x \sin y + 3y$ and $N(x,y) = -3x + e^x \sin y$. Note that $M_y \neq N_x$, and hence the differential equation is not exact.

10. $M(x,y) = y/x+6x$ and $N(x,y) = \ln x - 2$. Since $M_y = N_x = 1/x$, the given equation is exact. Integrating N with respect to y, while holding x constant, results in $\psi(x,y) = y \ln x - 2y + h(x)$. Differentiating with respect to x, $\psi_x = y/x + h'(x)$. Setting $\psi_x = M$, we find that $h'(x) = 6x$, and hence $h(x) = 3x^2$. Therefore the solution is defined implicitly as $3x^2 + y \ln x - 2y = c$.

11. $M(x,y) = x \ln y + xy$ and $N(x,y) = y \ln x + xy$. Note that $M_y \neq N_x$, and hence the differential equation is not exact.

13. $M(x,y) = 2x-y$ and $N(x,y) = 2y-x$. Since $M_y = N_x = -1$, the equation is exact. Integrating M with respect to x, while holding y constant, yields $\psi(x,y) = x^2-xy+h(y)$. Now $\psi_y = -x+h'(y)$. Equating ψ_y with N results in $h'(y) = 2y$, and hence $h(y) = y^2$. Thus $\psi(x,y) = x^2-xy+y^2$, and the solution is given implicitly as $x^2-xy+y^2 = c$. Invoking the initial condition $y(1) = 3$, the specific solution is $x^2-xy+y^2 = 7$. The explicit form of the solution is $y(x) = (x+\sqrt{28-3x^2}\,)/2$. Hence the solution is valid as long as $3x^2 \leq 28$.

16. $M(x,y) = y\,e^{2xy}+x$ and $N(x,y) = bx\,e^{2xy}$. Note that $M_y = e^{2xy}+2xy\,e^{2xy}$, and $N_x = b\,e^{2xy}+2bxy\,e^{2xy}$. The given equation is exact, as long as $b = 1$. Integrating N with respect to y, while holding x constant, results in $\psi(x,y) = e^{2xy}/2+h(x)$. Now differentiating with respect to x, $\psi_x = y\,e^{2xy}+h'(x)$. Setting $\psi_x = M$, we find that $h'(x) = x$, and hence $h(x) = x^2/2$. We conclude that $\psi(x,y) = e^{2xy}/2+x^2/2$. Hence the solution is given implicitly as $e^{2xy}+x^2 = c$.

17. Note that ψ is of the form $\psi(x\,,y) = f(x) + g(y)$, since each of the integrands is a function of a single variable. It follows that

$$\psi_x = \frac{df}{dx} \text{ and } \psi_y = \frac{dg}{dx}\,.$$

That is,

$$\psi_x = M(x\,,y_0) \text{ and } \psi_y = N(x_0\,,y)\,.$$

Furthermore,

$$\frac{\partial^2\psi}{\partial x\partial y}(x_0\,,y_0\,) = \frac{\partial M}{\partial y}(x_0\,,y_0\,) \text{ and } \frac{\partial^2\psi}{\partial y\partial x}(x_0\,,y_0\,) = \frac{\partial N}{\partial x}(x_0\,,y_0\,)\,.$$

Based on the hypothesis and the fact that the point (x_0, y_0) is arbitrary, $\psi_{xy} = \psi_{yx}$ and

$$\frac{\partial M}{\partial y}(x, y) = \frac{\partial N}{\partial x}(x, y\,)\,.$$

18. Observe that $\frac{\partial}{\partial y}\,[M(x)] = \frac{\partial}{\partial x}\,[N(y)] = 0\,.$

20. $M_y = y^{-1}\cos\,y - y^{-2}\sin\,y$ and $N_x = -2\,e^{-x}(\cos\,x + \sin\,x)/y\,.$ Multiplying both sides by the integrating factor $\mu(x, y) = y\,e^x$, the given equation can be written as $(e^x\sin\,y - 2y\,\sin\,x)dx + (e^x\cos\,y + 2\cos\,x)dy = 0\,.$ Let $\overline{M} = \mu M$ and $\overline{N} = \mu N$. Observe that $\overline{M}_y = \overline{N}_x$, and hence the latter ODE is exact. Integrating $\overline{N}$ with respect to y , while holding x constant, results in $\psi(x, y) = e^x\sin\,y + 2y\,\cos\,x + h(x)\,.$ Now differentiating with respect to x, $\psi_x = e^x\sin\,y - 2y\,\sin\,x + h'(x)$. Setting $\psi_x = \overline{M}$, we find that $h'(x) = 0\,,$ and hence $h(x) = 0$ is feasible. Hence the solution of the given equation is defined implicitly by $e^x\sin\,y + 2y\,\cos\,x = c$.

21. $M_y = 1$ and $N_x = 2\,.$ Multiply both sides by the integrating factor $\mu(x, y) = y$ to obtain $y^2dx + (2xy - y^2e^y)dy = 0$. Let $\overline{M} = yM$ and $\overline{N} = yN$. It is easy to see that $\overline{M}_y = \overline{N}_x$, and hence the latter ODE is exact. Integrating $\overline{M}$ with respect to x yields $\psi(x, y) = xy^2 + h(y)\,.$ Equating ψ_y with $\overline{N}$ results in $h'(y) = -y^2e^y$, and hence $h(y) = -e^y(y^2 - 2y + 2)$. Thus $\psi(x, y) = xy^2 - e^y(y^2 - 2y + 2)$, and the solution is defined implicitly by $xy^2 - e^y(y^2 - 2y + 2) = c\,.$

24. The equation $\mu M + \mu N y' = 0$ has an integrating factor if $(\mu M)_y = (\mu N)_x$, that is, $\mu_y M - \mu_x N = \mu N_x - \mu M_y\,.$ Suppose that $N_x - M_y = R\,(xM - yN)$, in which R is some function depending only on the quantity $z = xy\,.$ It follows that the modified form of the equation is exact, if $\mu_y M - \mu_x N = \mu R\,(xM - yN) = R\,(\mu\,xM - \mu\,yN)$. This relation is satisfied if $\mu_y = (\mu\,x)R$ and $\mu_x = (\mu\,y)R\,.$ Now consider $\mu = \mu(xy)$. Then the partial derivatives are $\mu_x = \mu' y$ and $\mu_y = \mu' x\,.$ Note that $\mu' = d\mu/dz\,.$ Thus μ must satisfy $\mu'(z) = R(z)$. The latter equation is separable, with $d\mu = R(z)dz$, and $\mu(z) = \int R(z)dz\,.$ Therefore, given $R = R(xy)$, it is possible to determine $\mu = \mu(xy)$ which becomes an integrating factor of the differential equation.

28. The equation is not exact, since $N_x - M_y = 2y - 1\,.$ However, $(N_x - M_y)/M = (2y - 1)/y$ is a function of y alone. Hence there exists $\mu = \mu(y)$, which is a solution

of the differential equation $\mu' = (2 - 1/y)\mu$. The latter equation is separable, with $d\mu/\mu = 2 - 1/y$. One solution is $\mu(y) = e^{2y - \ln y} = e^{2y}/y$. Now rewrite the given ODE as $e^{2y}dx + (2x\,e^{2y} - 1/y)dy = 0$. This equation is exact, and it is easy to see that $\psi(x, y) = x\,e^{2y} - \ln y$. Therefore the solution of the given equation is defined implicitly by $x\,e^{2y} - \ln y = c$.

30. The given equation is not exact, since $N_x - M_y = 8x^3/y^3 + 6/y^2$. But note that $(N_x - M_y)/M = 2/y$ is a function of y alone, and hence there is an integrating factor $\mu = \mu(y)$. Solving the equation $\mu' = (2/y)\mu$, an integrating factor is $\mu(y) = y^2$. Now rewrite the differential equation as $(4x^3 + 3y)dx + (3x + 4y^3)dy = 0$. By inspection, $\psi(x, y) = x^4 + 3xy + y^4$, and the solution of the given equation is defined implicitly by $x^4 + 3xy + y^4 = c$.

32. Multiplying both sides of the ODE by $\mu = [xy(2x + y)]^{-1}$, the given equation is equivalent to $\left[(3x + y)/(2x^2 + xy)\right] dx + \left[(x + y)/(2xy + y^2)\right] dy = 0$. Rewrite the differential equation as

$$\left[\frac{2}{x} + \frac{2}{2x + y}\right] dx + \left[\frac{1}{y} + \frac{1}{2x + y}\right] dy = 0 \,.$$

It is easy to see that $M_y = N_x$. Integrating M with respect to x, while keeping y constant, results in $\psi(x, y) = 2\ln|x| + \ln|2x + y| + h(y)$. Now taking the partial derivative with respect to y , $\psi_y = (2x + y)^{-1} + h'(y)$. Setting $\psi_y = N$, we find that $h'(y) = 1/y$, and hence $h(y) = \ln\,|y|$. Therefore

$$\psi(x, y) = 2\ln|x| + \ln|2x + y| + \ln\,|y| \,,$$

and the solution of the given equation is defined implicitly by $2x^3y + x^2y^2 = c$.

2.7

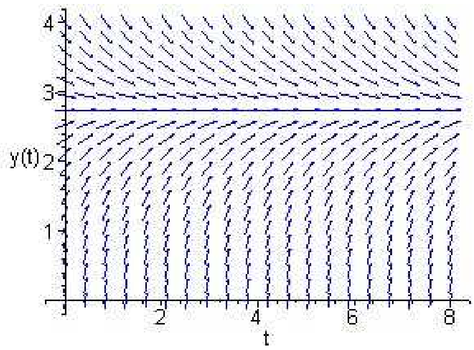
2.(a) The Euler formula is $y_{n+1} = y_n + h(2y_n - 1) = (1 + 2h)y_n - h$. Numerical results: 1.1, 1.22, 1.364, 1.5368.

(d) The differential equation is linear, with solution $y(t) = (1 + e^{2t})/2$.

4.(a) The Euler formula is $y_{n+1} = (1 - 2h)y_n + 3h\cos t_n$. Numerical results: 0.3, 0.5385, 0.7248, 0.8665.

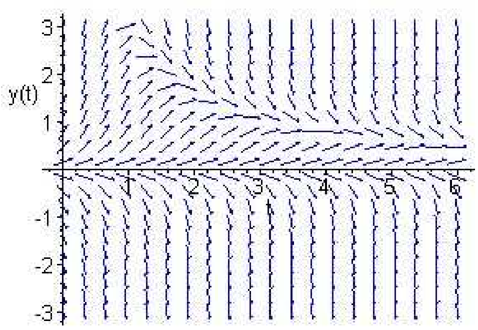
(d) The exact solution is $y(t) = (6\cos t + 3\sin t - 6\,e^{-2t})/5$.

5.



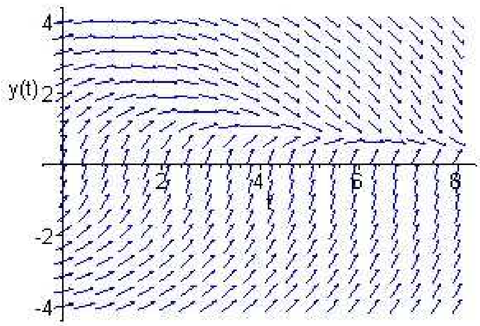
All solutions seem to converge to $y = 25/9$.

6.



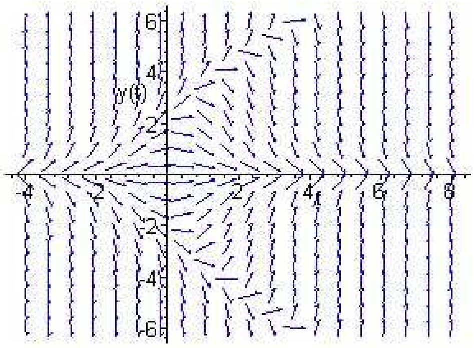
Solutions with positive initial conditions seem to converge to a specific function. On the other hand, solutions with negative coefficients decrease without bound. $y = 0$ is an equilibrium solution.

7.



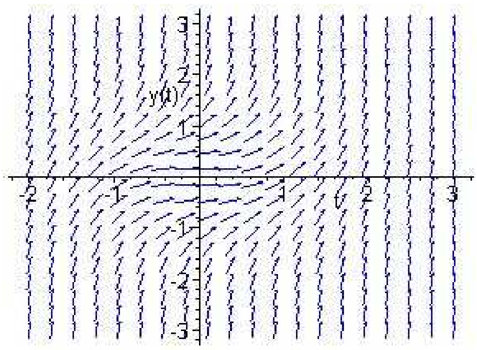
All solutions seem to converge to a specific function.

8.



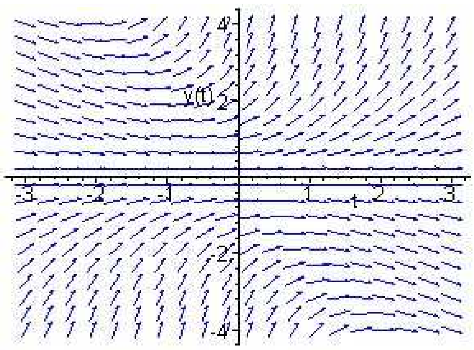
Solutions with initial conditions to the "left" of the curve $t = 0.1y^2$ seem to diverge. On the other hand, solutions to the "right" of the curve seem to converge to zero. Also, $y = 0$ is an equilibrium solution.

9.



All solutions seem to diverge.

10.



Solutions with positive initial conditions increase without bound. Solutions with negative initial conditions decrease without bound. Note that $y = 0$ is an equilibrium solution.

11. The Euler formula is $y_{n+1} = y_n - 3h\sqrt{y_n} + 5h$ and $(t_0, y_0) = (0, 2)$.

12. The iteration formula is $y_{n+1} = (1+3h)y_n - h\,t_n\,y_n^2$ and $(t_0, y_0) = (0, 0.5)$.

14. The iteration formula is $y_{n+1} = (1 - h\,t_n\,)y_n + h\,y_n^3\,/10$ and $(t_0, y_0) = (0, 1)$.

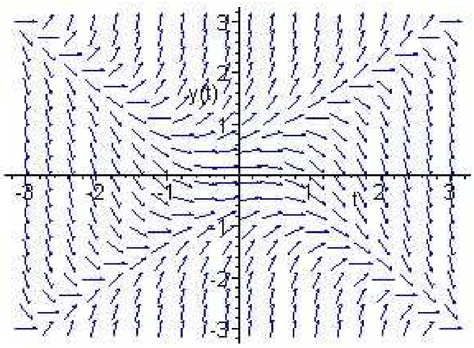
17. The Euler formula is

$$y_{n+1} = y_n + \frac{h(y_n^2 + 2t_n\,y_n)}{3 + t_n^2}.$$

The initial point is $(t_0, y_0) = (1\,, 2)$. Using this iteration formula with the specified h values, the value of the solution at $t = 2.5$ is somewhere between 18 and 19. At $t = 3$ there is no reliable estimate.

18.(a) See Problem 8.

19.(a)



(b) The iteration formula is $y_{n+1} = y_n + h\,y_n^2\, - h\,t_n^2\,$. The critical value of α appears to be near $\alpha_0 \approx 0.6815\,$. For $y_0 > \alpha_0\,$, the iterations diverge.

20.(a) The ODE is linear, with general solution $y(t) = t + ce^t$. Invoking the specified initial condition, $y(t_0) = y_0$, we have $y_0 = t_0 + ce^{t_0}$. Hence $c = (y_0 - t_0)e^{-t_0}$. Thus the solution is given by $\phi(t) = (y_0 - t_0)e^{t-t_0} + t$.

(b) The Euler formula is $y_{n+1} = (1+h)y_n + h - h\,t_n\,$. Now set $k = n+1\,$.

(c) We have $y_1 = (1+h)y_0 + h - ht_0 = (1+h)y_0 + (t_1 - t_0) - ht_0$. Rearranging the terms, $y_1 = (1+h)(y_0 - t_0) + t_1$. Now suppose that $y_k = (1+h)^k(y_0 - t_0) + t_k$, for some $k \geq 1$. Then $y_{k+1} = (1+h)y_k + h - ht_k$. Substituting for y_k, we find that

$$y_{k+1} = (1+h)^{k+1}(y_0 - t_0) + (1+h)t_k + h - ht_k = (1+h)^{k+1}(y_0 - t_0) + t_k + h.$$

Noting that $t_{k+1} = t_k + k$, the result is verified.

(d) Substituting $h = (t - t_0)/n\,$, with $t_n = t\,$,

$$y_n = (1 + \frac{t - t_0}{n})^n (y_0 - t_0) +\, t\,.$$

Taking the limit of both sides, as $n \to \infty$, and using the fact that

$$\lim_{n\to\infty}(1+a/n)^n = e^a,$$

pointwise convergence is proved.

21. The exact solution is $y(t) = e^t$. The Euler formula is $y_{n+1} = (1+h)y_n$. It is easy to see that $y_n = (1+h)^n y_0 = (1+h)^n$. Given $t > 0$, set $h = t/n$. Taking the limit, we find that $\lim_{n\to\infty} y_n = \lim_{n\to\infty}(1+t/n)^n = e^t$.

23. The exact solution is $y(t) = t/2 + e^{2t}$. The Euler formula is

$$y_{n+1} = (1+2h)y_n + h/2 - h\,t_n\,.$$

Since $y_0 = 1$, $y_1 = (1+2h) + h/2 = (1+2h) + t_1/2$. It is easy to show by mathematical induction, that $y_n = (1+2h)^n + t_n/2$. For $t > 0$, set $h = t/n$ and thus $t_n = t$. Taking the limit, we find that

$$\lim_{n\to\infty} y_n = \lim_{n\to\infty}\left[(1+2t/n)^n + t/2\right] = e^{2t} + t/2.$$

Hence pointwise convergence is proved.

2.8

2. Let $z = y - 3$ and $\tau = t + 1$. It follows that $dz/d\tau = (dz/dt)(dt/d\tau) = dz/dt$. Furthermore, $dz/dt = dy/dt = 1 - y^3$. Hence $dz/d\tau = 1 - (z+3)^3$. The new initial condition is $z(\tau = 0) = 0$.

3. The approximating functions are defined recursively by

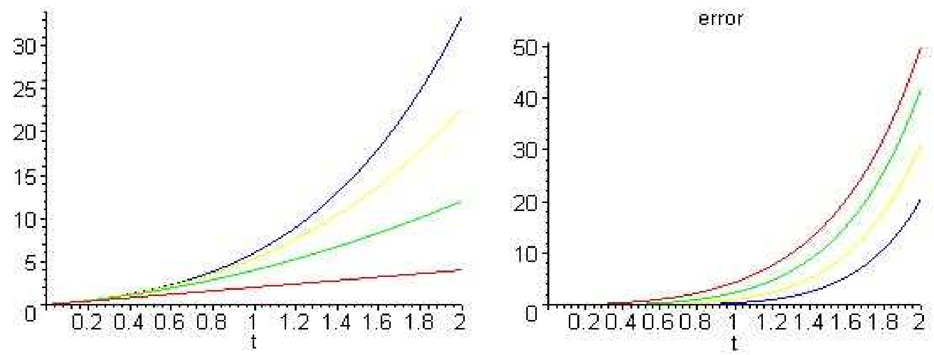
$$\phi_{n+1}(t) = \int_0^t 2\left[\phi_n(s) + 1\right] ds\,.$$

Setting $\phi_0(t) = 0$, $\phi_1(t) = 2t$. Continuing, $\phi_2(t) = 2t^2 + 2t$, $\phi_3(t) = \frac{4}{3}t^3 + 2t^2 + 2t$, $\phi_4(t) = \frac{2}{3}t^4 + \frac{4}{3}t^3 + 2t^2 + 2t$, ... Given convergence, set

$$\phi(t) = \phi_1(t) + \sum_{k=1}^{\infty}\left[\phi_{k+1}(t) - \phi_k(t)\right] = 2t + \sum_{k=2}^{\infty}\frac{a_k}{k\,!}t^k\,.$$

Comparing coefficients, $a_3/3! = 4/3$, $a_4/4! = 2/3$, ... It follows that $a_3 = 8$, $a_4 = 16$, and so on. We find that in general $a_k = 2^k$. Hence

$$\phi(t) = \sum_{k=1}^{\infty}\frac{2^k}{k\,!}t^k = e^{2t} - 1\,.$$



5. The approximating functions are defined recursively by

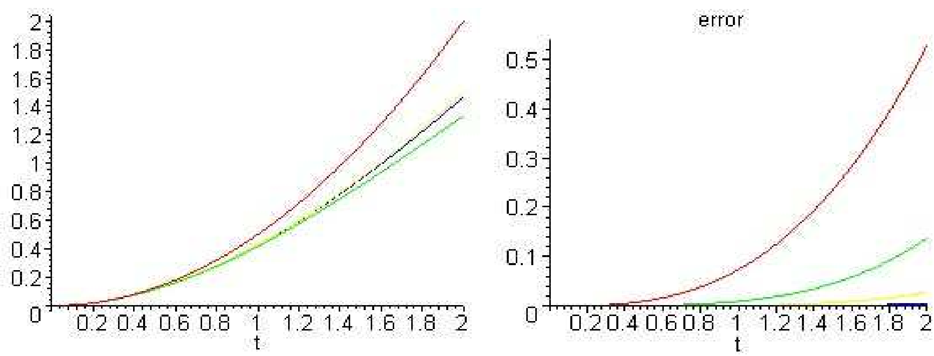
$$\phi_{n+1}(t) = \int_0^t \left[-\phi_n(s)/2 + s\right] ds\,.$$

Setting $\phi_0(t) = 0$, $\phi_1(t) = t^2/2$. Continuing, $\phi_2(t) = t^2/2 - t^3/12$, $\phi_3(t) = t^2/2 - t^3/12 + t^4/96$, $\phi_4(t) = t^2/2 - t^3/12 + t^4/96 - t^5/960$, $\ldots$. Given convergence, set

$$\phi(t) = \phi_1(t) + \sum_{k=1}^{\infty}\left[\phi_{k+1}(t) - \phi_k(t)\right] = t^2/2 + \sum_{k=3}^{\infty} \frac{a_k}{k\,!}t^k\,.$$

Comparing coefficients, $a_3/3! = -1/12\,,\; a_4/4! = 1/96\,,\; a_5/5! = -1/960\,,\;\ldots.$ We find that $a_3 = -1/2\,,\; a_4 = 1/4,\; a_5 = -1/8\,,\;\ldots.$ In general, $a_k = 2^{-k+1}$. Hence

$$\phi(t) = \sum_{k=2}^{\infty} \frac{2^{-k+2}}{k\,!}(-t)^k = 4\,e^{-t/2} + 2t - 4\,.$$



6. The approximating functions are defined recursively by

$$\phi_{n+1}(t) = \int_0^t \left[\phi_n(s) + 1 - s\right] ds\,.$$

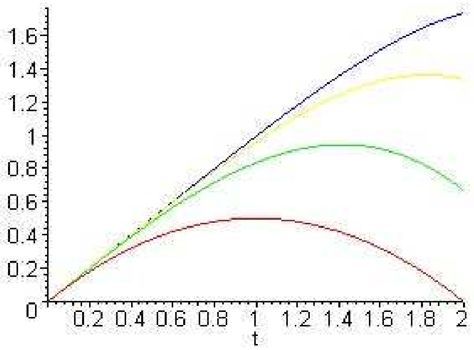
Setting $\phi_0(t) = 0$, $\phi_1(t) = t - t^2/2$, $\phi_2(t) = t - t^3/6$, $\phi_3(t) = t - t^4/24$, $\phi_4(t) = t -$

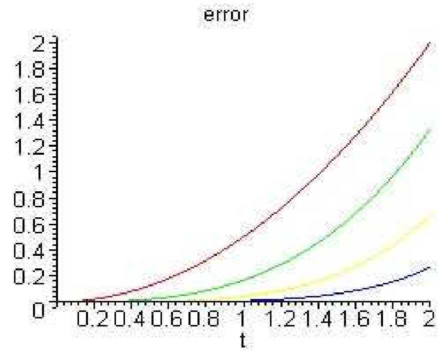
$t^5/120, \ldots$. Given convergence, set

$$\phi(t) = \phi_1(t) + \sum_{k=1}^{\infty} [\phi_{k+1}(t) - \phi_k(t)] =$$

$$= t - t^2/2 + \left[t^2/2 - t^3/6\right] + \left[t^3/6 - t^4/24\right] + \ldots = t + 0 + 0 + \ldots.$$

Note that the terms can be rearranged, as long as the series converges uniformly.





8.(a) The approximating functions are defined recursively by

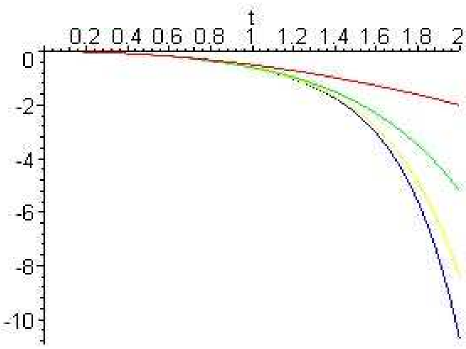
$$\phi_{n+1}(t) = \int_0^t \left[s^2\phi_n(s) - s\right] ds\,.$$

Set $\phi_0(t) = 0$. The iterates are given by $\phi_1(t) = -t^2/2$, $\phi_2(t) = -t^2/2 - t^5/10$, $\phi_3(t) = -t^2/2 - t^5/10 - t^8/80$, $\phi_4(t) = -t^2/2 - t^5/10 - t^8/80 - t^{11}/880, \ldots$. Upon inspection, it becomes apparent that

$$\phi_n(t) = -t^2\left[\frac{1}{2} + \frac{t^3}{2\cdot 5} + \frac{t^6}{2\cdot 5\cdot 8} + \ldots + \frac{(t^3)^{n-1}}{2\cdot 5\cdot 8\ldots[2+3(n-1)]}\right] =$$

$$= -t^2\sum_{k=1}^{n}\frac{(t^3)^{k-1}}{2\cdot 5\cdot 8\ldots[2+3(k-1)]}.$$

(b)



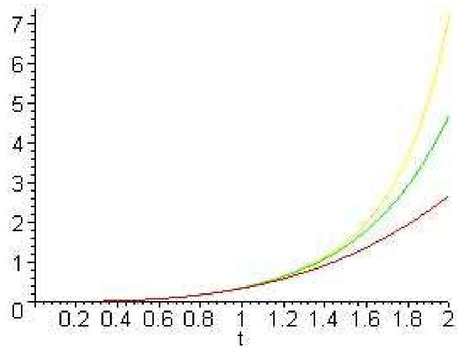
The iterates appear to be converging.

9.(a) The approximating functions are defined recursively by

$$\phi_{n+1}(t) = \int_0^t \left[s^2 + \phi_n^2(s)\right] ds\,.$$

Set $\phi_0(t) = 0$. The first three iterates are given by $\phi_1(t) = t^3/3$, $\phi_2(t) = t^3/3 + t^7/63$, $\phi_3(t) = t^3/3 + t^7/63 + 2t^{11}/2079 + t^{15}/59535$.

(b)



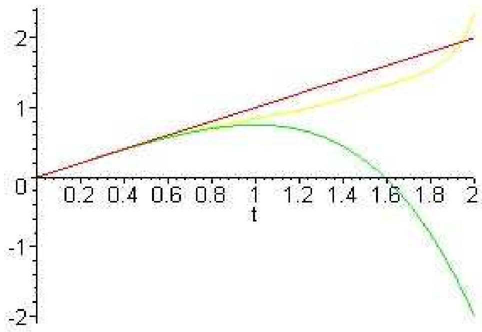
The iterates appear to be converging.

10.(a) The approximating functions are defined recursively by

$$\phi_{n+1}(t) = \int_0^t \left[1 - \phi_n^3(s)\right] ds\,.$$

Set $\phi_0(t) = 0$. The first three iterates are given by $\phi_1(t) = t$, $\phi_2(t) = t - t^4/4$, $\phi_3(t) = t - t^4/4 + 3t^7/28 - 3t^{10}/160 + t^{13}/832$.

(b)



The approximations appear to be diverging.

12.(a) The approximating functions are defined recursively by

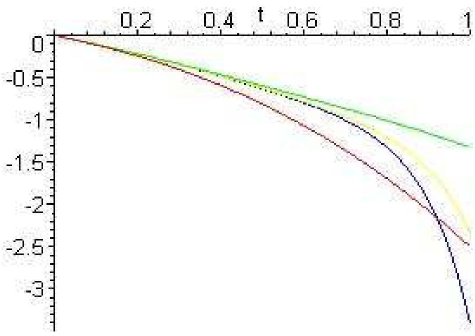
$$\phi_{n+1}(t) = \int_0^t \left[\frac{3s^2+4s+2}{2(\phi_n(s)-1)}\right] ds\,.$$

Note that $1/(2y-2) = -\frac{1}{2}\sum_{k=0}^{6} y^k + O(y^7)$. For computational purposes, use the geometric series sum to replace the above iteration formula by

$$\phi_{n+1}(t) = -\frac{1}{2}\int_0^t \left[(3s^2+4s+2)\sum_{k=0}^{6}\phi_n^k(s)\right] ds\,.$$

Set $\phi_0(t)=0$. The first four approximations are given by $\phi_1(t) = -t-t^2-t^3/2$, $\phi_2(t) = -t-t^2/2+t^3/6+t^4/4-t^5/5-t^6/24+\ldots$, $\phi_3(t) = -t-t^2/2+t^4/12-3t^5/20+4t^6/45+\ldots$, $\phi_4(t) = -t-t^2/2+t^4/8-7t^5/60+t^6/15+\ldots$

(b)



The approximations appear to be converging to the exact solution,

$$\phi(t) = 1-\sqrt{1+2t+2t^2+t^3}\,.$$

13. Note that $\phi_n(0)=0$ and $\phi_n(1)=1$, for every $n\geq 1$. Let $a\in(0,1)$. Then $\phi_n(a)=a^n$. Clearly, $\lim_{n\to\infty} a^n = 0$. Hence the assertion is true.

14.(a) $\phi_n(0)=0$, for every $n\geq 1$. Let $a\in(0,1]$. Then $\phi_n(a) = 2na\,e^{-na^2} = 2na/e^{na^2}$. Using l'Hospital's rule,

$$\lim_{z\to\infty} 2az/e^{az^2} = \lim_{z\to\infty} 1/ze^{az^2} = 0.$$

Hence $\lim_{n\to\infty}\phi_n(a)=0$.

(b) $\int_0^1 2nx\,e^{-nx^2}dx = -e^{-nx^2}\big|_0^1 = 1-e^{-n}$. Therefore,

$$\lim_{n\to\infty}\int_0^1 \phi_n(x)dx \neq \int_0^1 \lim_{n\to\infty}\phi_n(x)dx\,.$$

15. Let t be fixed, such that $(t\,,y_1),(t\,,y_2)\in D$. Without loss of generality, assume that $y_1<y_2$. Since f is differentiable with respect to y, the mean value theorem asserts that there exists $\xi\in(y_1\,,y_2)$ such that $f(t\,,y_1)-f(t\,,y_2) = f_y(t\,,\xi)(y_1-y_2)$.

This means that $|f(t\,,y_1)-f(t\,,y_2)|=|f_y(t\,,\xi)|\;|y_1-y_2|$. Since, by assumption, $\partial f/\partial y$ is continuous in D, f_y attains a maximum on any closed and bounded subset of D. Hence

$$|f(t\,,y_1)-f(t\,,y_2)|\leq K\;|y_1-y_2|\,.$$

16. For a sufficiently small interval of t, $\phi_{n-1}(t)$, $\phi_n(t)\in D$. Since f satisfies a Lipschitz condition, $|f(t,\phi_n(t))-f(t,\phi_{n-1}(t))|\leq K\,|\phi_n(t)-\phi_{n-1}(t)|$. Here $K=\max|f_y|$.

17.(a) $\phi_1(t)=\int_0^t f(s\,,0)ds$. Hence $|\phi_1(t)|\leq\int_0^{|t|}|f(s\,,0)|\,ds\leq\int_0^{|t|}Mds=M\,|t|$, in which M is the maximum value of $|f(t\,,y)|$ on D.

(b) By definition, $\phi_2(t)-\phi_1(t)=\int_0^t[f(s\,,\phi_1(s))-f(s\,,0)]\,ds$. Taking the absolute value of both sides, $|\phi_2(t)-\phi_1(t)|\leq\int_0^{|t|}|[f(s\,,\phi_1(s))-f(s\,,0)]|\,ds$. Based on the results in Problems 16 and 17,

$$|\phi_2(t)-\phi_1(t)|\leq\int_0^{|t|}K\,|\phi_1(s)-0|\,ds\leq KM\int_0^{|t|}|s|\,ds\,.$$

Evaluating the last integral, we obtain that $|\phi_2(t)-\phi_1(t)|\leq MK\,|t|^2/2$.

(c) Suppose that

$$|\phi_i(t)-\phi_{i-1}(t)|\leq\frac{MK^{i-1}\,|t|^i}{i!}$$

for some $i\geq1$. By definition,

$$\phi_{i+1}(t)-\phi_i(t)=\int_0^t[f(s,\phi_i(s))-f(s,\phi_{i-1}(s))]\,ds\,.$$

It follows that

$$|\phi_{i+1}(t)-\phi_i(t)|\leq\int_0^{|t|}|f(s,\phi_i(s))-f(s,\phi_{i-1}(s))|\,ds\leq$$

$$\leq\int_0^{|t|}K\,|\phi_i(s)-\phi_{i-1}(s)|\,ds\leq\int_0^{|t|}K\frac{MK^{\,i-1}\,|s|^i}{i!}ds=$$

$$=\frac{MK^{\,i}\,|t|^{i+1}}{(i+1)!}\leq\frac{MK^{\,i}h^{i+1}}{(i+1)!}\,.$$

Hence, by mathematical induction, the assertion is true.

18.(a) Use the triangle inequality, $|a+b|\leq|a|+|b|$.

(b) For $|t|\leq h$, $|\phi_1(t)|\leq Mh$, and $|\phi_n(t)-\phi_{n-1}(t)|\leq MK^{\,n-1}h^n/(n\,!)$. Hence

$$|\phi_n(t)|\leq M\sum_{i=1}^{n}\frac{K^{\,i-1}h^i}{i\,!}=\frac{M}{K}\sum_{i=1}^{n}\frac{(Kh)^i}{i\,!}\,.$$

(c) The sequence of partial sums in (b) converges to $M(e^{Kh}-1)/K$. By the comparison test, the sums in (a) also converge. Furthermore, the sequence $|\phi_n(t)|$ is bounded, and hence has a convergent subsequence. Finally, since individual terms of the series must tend to zero, $|\phi_n(t)-\phi_{n-1}(t)| \to 0$, and it follows that the sequence $|\phi_n(t)|$ is convergent.

19.(a) Let $\phi(t)=\int_0^t f(s\,,\phi(s))ds$ and $\psi(t)=\int_0^t f(s\,,\psi(s))ds$. Then by linearity of the integral, $\phi(t)-\psi(t)=\int_0^t [f(s\,,\phi(s))-f(s\,,\psi(s))]\,ds$.

(b) It follows that $|\phi(t)-\psi(t)| \leq \int_0^t |f(s\,,\phi(s))-f(s\,,\psi(s))|\,ds$.

(c) We know that f satisfies a Lipschitz condition,

$$|f(t\,,y_1)-f(t\,,y_2)| \leq K\,|y_1-y_2|\,,$$

based on $|\partial f/\partial y| \leq K$ in D. Therefore,

$$\begin{aligned}|\phi(t)-\psi(t)| &\leq \int_0^t |f(s\,,\phi(s))-f(s\,,\psi(s))|\,ds \\ &\leq \int_0^t K\,|\phi(s)-\psi(s)|\,ds\,.\end{aligned}$$

2.9

1. Writing the equation for each $n \geq 0$, $y_1=-0.9\,y_0$, $y_2=-0.9\,y_1$, $y_3=-0.9\,y_2$ and so on, it is apparent that $y_n=(-0.9)^n\,y_0$. The terms constitute an alternating series, which converge to zero, regardless of y_0.

3. Write the equation for each $n \geq 0$, $y_1=\sqrt{3}\,y_0$, $y_2=\sqrt{4/2}\,y_1$, $y_3=\sqrt{5/3}\,y_2$, ... Upon substitution, we find that $y_2=\sqrt{(4\cdot 3)/2}\,y_1$, $y_3=\sqrt{(5\cdot 4\cdot 3)/(3\cdot 2)}\,y_0$, ... It can be proved by mathematical induction, that

$$\begin{aligned}y_n &= \frac{1}{\sqrt{2}}\sqrt{\frac{(n+2)!}{n!}}\;y_0 \\ &= \frac{1}{\sqrt{2}}\sqrt{(n+1)(n+2)}\;y_0\,.\end{aligned}$$

This sequence is divergent, except for $y_0=0$.

4. Writing the equation for each $n \geq 0$, $y_1=-y_0$, $y_2=y_1$, $y_3=-y_2$, $y_4=y_3$, and so on. It can be shown that

$$y_n=\begin{cases} y_0, & \text{for } n=4k \text{ or } n=4k-1 \\ -y_0, & \text{for } n=4k-2 \text{ or } n=4k-3\end{cases}$$

The sequence is convergent only for $y_0=0$.

5. Writing the equation for each $n \geq 0$,

$$
\begin{aligned}
y_1 &= 0.5\, y_0 + 6 \\
y_2 &= 0.5\, y_1 + 6 = 0.5(0.5\, y_0 + 6) + 6 = (0.5)^2 y_0 + 6 + (0.5)6 \\
y_3 &= 0.5\, y_2 + 6 = 0.5(0.5\, y_1 + 6) + 6 = (0.5)^3 y_0 + 6\left[1 + (0.5) + (0.5)^2\right] \\
&\vdots \\
y_n &= (0.5)^n y_0 + 12\left[1 - (0.5)^n\right],
\end{aligned}
$$

which follows from Eq.(13) and (14). The sequence is convergent for all y_0, and in fact $y_n \to 12$.

6. Writing the equation for each $n \geq 0$,

$$
\begin{aligned}
y_1 &= -0.5\, y_0 + 6 \\
y_2 &= -0.5\, y_1 + 6 = -0.5(-0.5\, y_0 + 6) + 6 = (-0.5)^2 y_0 + 6 + (-0.5)6 \\
y_3 &= -0.5\, y_2 + 6 = -0.5(-0.5\, y_1 + 6) + 6 = (-0.5)^3 y_0 + 6\left[1 + (-0.5) + (-0.5)^2\right] \\
&\vdots \\
y_n &= (-0.5)^n y_0 + 4\left[1 - (-0.5)^n\right]
\end{aligned}
$$

which follows from Eq.(13) and (14). The sequence is convergent for all y_0, and in fact $y_n \to 4$.

7. Let y_n be the balance at the end of the nth day. Then $y_{n+1} = (1 + r/356)\, y_n$. The solution of this difference equation is $y_n = (1 + r/365)^n\, y_0$, in which y_0 is the initial balance. At the end of one year, the balance is $y_{365} = (1 + r/365)^{365}\, y_0$. Given that $r = .07$, $y_{365} = (1 + r/365)^{365}\, y_0 = 1.0725\, y_0$. Hence the effective annual yield is $(1.0725\, y_0 - y_0)/y_0 = 7.25\%$.

8. Let y_n be the balance at the end of the nth month. Then $y_{n+1} = (1 + r/12)y_n + 25$. As in the previous solutions, we have

$$y_n = \rho^n\left[y_0 - \frac{25}{1-\rho}\right] + \frac{25}{1-\rho},$$

in which $\rho = (1 + r/12)$. Here r is the annual interest rate, given as 8%. Therefore $y_{36} = (1.0066)^{36}\left[1000 + \frac{12\cdot 25}{r}\right] - \frac{12\cdot 25}{r} = \$2,283.63$.

9. Let y_n be the balance due at the end of the nth month. The appropriate difference equation is $y_{n+1} = (1 + r/12)\, y_n - P$. Here r is the annual interest rate and P is the monthly payment. The solution, in terms of the amount borrowed, is given by

$$y_n = \rho^n\left[y_0 + \frac{P}{1-\rho}\right] - \frac{P}{1-\rho},$$

in which $\rho = (1 + r/12)$ and $y_0 = 8,000$. To figure out the monthly payment P, we require that $y_{36} = 0$. That is,

$$\rho^{36}\left[y_0 + \frac{P}{1-\rho}\right] = \frac{P}{1-\rho}.$$

After the specified amounts are substituted, we find the $P = \$258.14$.

11. Let y_n be the balance due at the end of the nth month. The appropriate difference equation is $y_{n+1} = (1 + r/12)\, y_n - P$, in which $r = .09$ and P is the monthly payment. The initial value of the mortgage is $y_0 = \$100,000$. Then the balance due at the end of the n-th month is

$$y_n = \rho^n \left[y_0 + \frac{P}{1-\rho} \right] - \frac{P}{1-\rho}\,.$$

where $\rho = (1 + r/12)$. In terms of the specified values,

$$y_n = (1.0075)^n \left[10^5 - \frac{12P}{r} \right] + \frac{12P}{r}\,.$$

Setting $n = 30 \cdot 12 = 360$, and $y_{360} = 0$, we find that $P = \$804.62$. For the monthly payment corresponding to a 20 year mortgage, set $n = 240$ and $y_{240} = 0$.

12. Let y_n be the balance due at the end of the nth month, with y_0 the initial value of the mortgage. The appropriate difference equation is $y_{n+1} = (1 + r/12)\, y_n - P$, in which $r = 0.1$ and $P = \$1000$ is the maximum monthly payment. Given that the life of the mortgage is 20 years, we require that $y_{240} = 0$. The balance due at the end of the n-th month is

$$y_n = \rho^n \left[y_0 + \frac{P}{1-\rho} \right] - \frac{P}{1-\rho}\,.$$

In terms of the specified values for the parameters, the solution of

$$(1.00833)^{240} \left[y_0 - \frac{12 \cdot 1000}{0.1} \right] = -\frac{12 \cdot 1000}{0.1}$$

is $y_0 = \$103,624.62$.

14. Let $u_n = (\rho - 1)/\rho + v_n$. Then $u_{n+1} = (\rho - 1)/\rho + v_{n+1}$ and the equation turns into

$$u_{n+1} = \frac{\rho - 1}{\rho} + v_{n+1} = \rho u_n (1 - u_n) = \rho(\frac{\rho - 1}{\rho} + v_n)(1 - \frac{\rho - 1}{\rho} - v_n).$$

Now this implies that

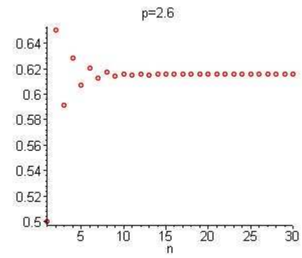
$$v_{n+1} = \rho(\frac{\rho - 1}{\rho} + v_n)(1 - \frac{\rho - 1}{\rho} - v_n) - \frac{\rho - 1}{\rho} =$$

$$= \rho(\frac{\rho - 1}{\rho} + v_n)(\frac{1}{\rho} - v_n) - \frac{\rho - 1}{\rho} = \rho(\frac{\rho - 1}{\rho^2} + v_n \frac{1}{\rho} - v_n \frac{\rho - 1}{\rho} - v_n^2) - \frac{\rho - 1}{\rho} =$$

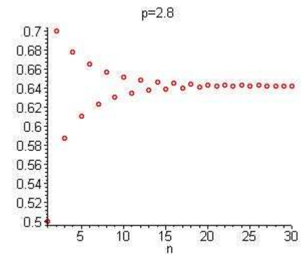
$$= \frac{\rho - 1}{\rho} + v_n - v_n \rho + v_n - \rho v_n^2 - \frac{\rho - 1}{\rho} = v_n (2 - \rho) - \rho v_n^2,$$

which is exactly what we wanted to prove.

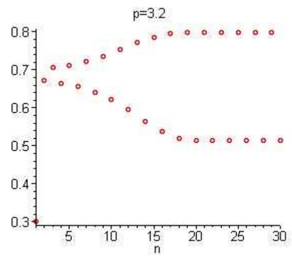
15.



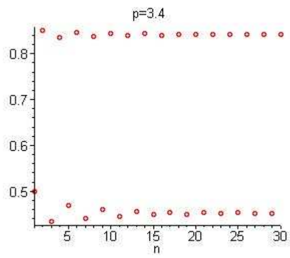
(a) $p = 2.6$



(b) $p = 2.8$

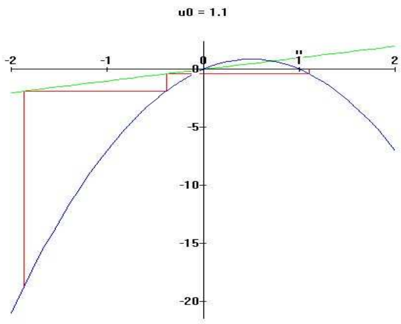


(c) $p = 3.2$



(d) $p = 3.4$

16. For example, take $\rho = 3.5$ and $u_0 = 1.1$:

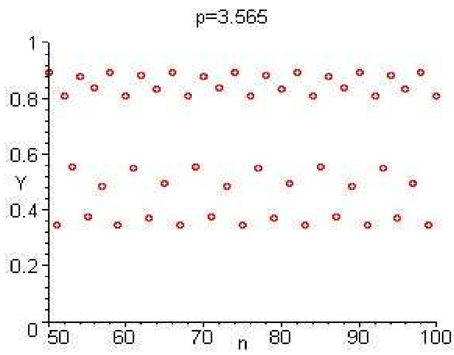


19.(a) $\delta_2 = (\rho_2 - \rho_1)/(\rho_3 - \rho_2) = (3.449 - 3)/(3.544 - 3.449) = 4.7263\,.$

(b) diff$= \frac{|\delta - \delta_2|}{\delta} \cdot 100 = \frac{|4.6692 - 4.7363|}{4.6692} \cdot 100 \approx 1.22.$

(c) Assuming $(\rho_3 - \rho_2)/(\rho_4 - \rho_3) = \delta\,,\ \rho_4 \approx 3.5643$

(d) A period 16 solutions appears near $\rho \approx 3.565\,.$



(e) Note that $(\rho_{n+1}-\rho_n)=\delta_n^{-1}(\rho_n-\rho_{n-1})$. With the assumption that $\delta_n=\delta$, we have $(\rho_{n+1}-\rho_n)=\delta^{-1}(\rho_n-\rho_{n-1})$, which is of the form $y_{n+1}=\alpha\, y_n\,,\ n\geq 3$. It follows that $(\rho_k-\rho_{k-1})=\delta^{3-k}(\rho_3-\rho_2)$ for $k\geq 4$. Then

$$\begin{aligned}\rho_n &= \rho_1+(\rho_2-\rho_1)+(\rho_3-\rho_2)+(\rho_4-\rho_3)+\ldots+(\rho_n-\rho_{n-1})\\ &= \rho_1+(\rho_2-\rho_1)+(\rho_3-\rho_2)\left[1+\delta^{-1}+\delta^{-2}+\ldots+\delta^{3-n}\right]\\ &= \rho_1+(\rho_2-\rho_1)+(\rho_3-\rho_2)\left[\frac{1-\delta^{4-n}}{1-\delta^{-1}}\right].\end{aligned}$$

Hence $\lim_{n\to\infty}\rho_n=\rho_2+(\rho_3-\rho_2)\left[\frac{\delta}{\delta-1}\right]$. Substitution of the appropriate values yields

$$\lim_{n\to\infty}\rho_n=3.5699$$

PROBLEMS

1. The equation is *linear*. It can be written in the form $y'+2y/x=x^2$, and the integrating factor is $\mu(x)=e^{\int(2/x)\,dx}=e^{2\ln x}=x^2$. Multiplication by $\mu(x)$ yields $x^2y'+2yx=(yx^2)'=x^4$. Integration with respect to x and division by x^2 gives that $y=x^3/5+c/x^2$.

2. The equation is *separable*. Separating the variables gives

$$(2-\sin y)dy=(1+\cos x)dx,$$

and after integration we obtain that the solution is $2y+\cos y-x-\sin x=c$.

3. The equation is *exact*. Algebraic manipulations yield the symmetric form

$$(2x+y)dx+(x-3-3y^2)dy=0.$$

We can check that $M_y=1=N_x$, so the equation is really exact. Integrating M with respect to x gives that

$$\psi(x,y)=x^2+xy+g(y),$$

then $\psi_y = x + g'(y) = x - 3 - 3y^2$, which means that $g'(y) = -3 - 3y^2$, so integrating with respect to y we obtain that $g(y) = -3y - y^3$. Therefore the solution is defined implicitly as $x^2 + xy - 3y - y^3 = c$. The initial condition $y(0) = 0$ implies that $c = 0$, so we conclude that the solution is $x^2 + xy - 3y - y^3 = 0$.

4. The equation is *separable*. Factoring the right hand side gives

$$y' = (1 - 2x)(3 + y).$$

Separation of variables leads to the equation

$$\frac{dy}{3 + y} = (1 - 2x)dx.$$

Integrating both sides gives $\ln|3 + y| = x - x^2 + \tilde{c}$. This means that $3 + y = ce^{x - x^2}$ and then $y = -3 + ce^{x - x^2}$.

5. The equation is *exact*. Algebraic manipulations give the symmetric form

$$(2xy + y^2 + 1)dx + (x^2 + 2xy)dy = 0.$$

We can check that $M_y = 2x + 2y = N_x$, so the equation is really exact. Integrating M with respect to x gives that

$$\psi(x, y) = x^2y + xy^2 + x + g(y),$$

then $\psi_y = x^2 + 2xy + g'(y) = x^2 + 2xy$, which means that $g'(y) = 0$, so we obtain that $g(y) = 0$ is acceptable. Therefore the solution is defined implicitly as

$$x^2y + xy^2 + x = c.$$

6. The equation is *linear*. It can be written in the form $y' + (1 + (1/x))y = 1/x$ and the integrating factor is $\mu(x) = e^{\int 1 + (1/x)\, dx} = e^{x + \ln x} = xe^x$. Multiplication by $\mu(x)$ yields $xe^x y' + (xe^x + e^x)y = (xe^x y)' = e^x$. Integration with respect to x and division by xe^x shows that the general solution of the equation is $y = 1/x + c/(xe^x)$. The initial condition implies that $0 = 1 + c/e$, which means that $c = -e$ and the solution is $y = 1/x - e/(xe^x) = x^{-1}(1 - e^{1-x})$.

7. The equation is *separable*. Separating the variables yields

$$y(2 + 3y)dy = (4x^3 + 1)dx,$$

and then after integration we obtain that the solution is $x^4 + x - y^2 - y^3 = c$.

8. The equation is *linear*. It can be written in the form $y' + 2y/x = \sin x/x^2$ and the integrating factor is $\mu(x) = e^{\int (2/x)\, dx} = e^{2\ln x} = x^2$. Multiplication by $\mu(x)$ gives $x^2y' + 2xy = (x^2y)' = \sin x$, and after integration with respect to x and division by x^2 we obtain the general solution $y = (c - \cos x)/x^2$. The initial condition implies that $c = 4 + \cos 2$ and the solution becomes $y = (4 + \cos 2 - \cos x)/x^2$.

9. The equation is *exact*. Algebraic manipulations give the symmetric form

$$(2xy + 1)dx + (x^2 + 2y)dy = 0.$$

We can check that $M_y = 2x = N_x$, so the equation is really exact. Integrating M with respect to x gives that $\psi(x,y) = x^2y + x + g(y)$, then $\psi_y = x^2 + g'(y) = x^2 + 2y$, which means that $g'(y) = 2y$, so we obtain that $g(y) = y^2$. Therefore the solution is defined implicitly as $x^2y + x + y^2 = c$.

10. The equation is *separable.* Factoring the terms we obtain the equation

$$(x^2 + x - 1)ydx + x^2(y-2)dy = 0.$$

We separate the variables by dividing this equation by yx^2 and obtain

$$(1 + \frac{1}{x} - \frac{1}{x^2})dx + (1 - \frac{2}{y})dy = 0.$$

Integration gives us the solution $x + \ln|x| + 1/x - 2\ln|y| + y = c$. We also have the solution $y = 0$ which we lost when we divided by y.

11. The equation is *exact.* It is easy to check that $M_y = 1 = N_x$. Integrating M with respect to x gives that $\psi(x,y) = x^3/3 + xy + g(y)$, then $\psi_y = x + g'(y) = x + e^y$, which means that $g'(y) = e^y$, so we obtain that $g(y) = e^y$. Therefore the solution is defined implicitly as $x^3/3 + xy + e^y = c$.

12. The equation is *linear.* The integrating factor is $\mu(x) = e^{\int dx} = e^x$, which turns the equation into $e^xy' + e^xy = (e^xy)' = e^x/(1+e^x)$. We can integrate the right hand side by substituting $u = 1 + e^x$, this gives us the solution $ye^x = \ln(1+e^x) + c$, i.e. $y = ce^{-x} + e^{-x}\ln(1+e^x)$.

13. The equation is *separable.* Factoring the right hand side leads to the equation $y' = (1+y^2)(1+2x)$. We separate the variables to obtain

$$\frac{dy}{1+y^2} = (1+2x)dx,$$

then integration gives us $\arctan y = x + x^2 + c$. The solution is

$$y = \tan(x + x^2 + c).$$

14. The equation is *exact.* We can check that $M_y = 1 = N_x$. Integrating M with respect to x gives that $\psi(x,y) = x^2/2 + xy + g(y)$, then $\psi_y = x + g'(y) = x + 2y$, which means that $g'(y) = 2y$, so we obtain that $g(y) = y^2$. Therefore the general solution is defined implicitly as $x^2/2 + xy + y^2 = c$. The initial condition gives us $c = 17$, so the solution is $x^2 + 2xy + 2y^2 = 34$.

15. The equation is *separable.* Separation of variables leads us to the equation

$$\frac{dy}{y} = \frac{1-e^x}{1+e^x}dx.$$

Note that $1 + e^x - 2e^x = 1 - e^x$. We obtain that

$$\ln|y| = \int \frac{1-e^x}{1+e^x}dx = \int 1 - \frac{2e^x}{1+e^x}dx = x - 2\ln(1+e^x) + \tilde{c}.$$

This means that $y = ce^x(1+e^x)^{-2}$, which also can be written as $y = c/\cosh^2(x/2)$ after some algebraic manipulations.

16. The equation is *exact*. The symmetric form is

$$(-e^{-x}\cos y + e^{2y}\cos x)dx + (-e^{-x}\sin y + 2e^{2y}\sin x)dy = 0.$$

We can check that $M_y = e^{-x}\sin y + 2e^{2y}\cos x = N_x$. Integrating M with respect to x gives that

$$\psi(x,y) = e^{-x}\cos y + e^{2y}\sin x + g(y),$$

then

$$\psi_y = -e^{-x}\sin y + 2e^{2y}\sin x + g'(y) = -e^{-x}\sin y + 2e^{2y}\sin x,$$

which means that $g'(y) = 0$, so we obtain that $g(y) = 0$ is acceptable. Therefore the solution is defined implicitly as $e^{-x}\cos y + e^{2y}\sin x = c$.

17. The equation is *linear*. The integrating factor is $\mu(x) = e^{-\int 3\,dx} = e^{-3x}$, which turns the equation into $e^{-3x}y' - 3e^{-3x}y = (e^{-3x}y)' = e^{-x}$. We integrate with respect to x to obtain $e^{-3x}y = -e^{-x} + c$, and the solution is $y = ce^{3x} - e^{2x}$ after multiplication by e^{3x}.

18. The equation is *linear*. The integrating factor is $\mu(x) = e^{\int 2\,dx} = e^{2x}$, which gives us $e^{2x}y' + 2e^{2x}y = (e^{2x}y)' = e^{-x^2}$. The antiderivative of the function on the right hand side can not be expressed in a closed form using elementary functions, so we have to express the solution using integrals. Let us integrate both sides of this equation from 0 to x. We obtain that the left hand side turns into

$$\int_0^x (e^{2s}y(s))'ds = e^{2x}y(x) - e^0y(0) = e^{2x}y - 3.$$

The right hand side gives us $\int_0^x e^{-s^2}\,ds$. So we found that

$$y = e^{-2x}\int_0^x e^{-s^2}\,ds + 3e^{-2x}.$$

19. The equation is *exact*. Algebraic manipulations give us the symmetric form $(y^3 + 2y - 3x^2)dx + (2x + 3xy^2)dy = 0$. We can check that $M_y = 3y^2 + 2 = N_x$. Integrating M with respect to x gives that $\psi(x,y) = xy^3 + 2xy - x^3 + g(y)$, then $\psi_y = 3xy^2 + 2x + g'(y) = 2x + 3xy^2$, which means that $g'(y) = 0$, so we obtain that $g(y) = 0$ is acceptable. Therefore the solution is $xy^3 + 2xy - x^3 = c$.

20. The equation is *separable*, because $y' = e^{x+y} = e^xe^y$. Separation of variables yields the equation $e^{-y}dy = e^xdx$, which turns into $-e^{-y} = e^x + c$ after integration and we obtain the implicitly defined solution $e^x + e^{-y} = c$.

21. The equation is *exact*. Algebraic manipulations give us the symmetric form $(2y^2 + 6xy - 4)dx + (3x^2 + 4xy + 3y^2)dy = 0$. We can check that $M_y = 4y + 6x = N_x$. Integrating M with respect to x gives that $\psi(x,y) = 2y^2x + 3x^2y - 4x + g(y)$, then $\psi_y = 4yx + 3x^2 + g'(y) = 3x^2 + 4xy + 3y^2$, which means that $g'(y) = 3y^2$, so we obtain that $g(y) = y^3$. Therefore the solution is $2xy^2 + 3x^2y - 4x + y^3 = c$.

22. The equation is *separable*. Separation of variables turns the equation into $(y^2+1)dy = (x^2-1)dx$, which, after integration, gives $y^3/3 + y = x^3/3 - x + c$. The initial condition yields $c = 2/3$, and the solution is $y^3 + 3y - x^3 + 3x = 2$.

23. The equation is *linear*. Division by t gives $y' + (1+(1/t))y = e^{2t}/t$, so the integrating factor is $\mu(t) = e^{\int(1+(1/t))dt} = e^{t+\ln t} = te^t$. The equation turns into $te^t y' + (te^t + e^t)y = (te^t y)' = e^{3t}$. Integration therefore leads to $te^t y = e^{3t}/3 + c$ and the solution is $y = e^{2t}/(3t) + ce^{-t}/t$.

24. The equation is *exact*. We can check that $M_y = 2\cos y \sin x \cos x = N_x$. Integrating M with respect to x gives that $\psi(x,y) = \sin y \sin^2 x + g(y)$, then $\psi_y = \cos y \sin^2 x + g'(y) = \cos y \sin^2 x$, which means that $g'(y) = 0$, so we obtain that $g(y) = 0$ is acceptable. Therefore the solution is defined implicitly as $\sin y \sin^2 x = c$.

25. The equation is *exact*. We can check that

$$M_y = -\frac{2x}{y^2} - \frac{x^2-y^2}{(x^2+y^2)^2} = N_x.$$

Integrating M with respect to x gives that $\psi(x,y) = x^2/y + \arctan(y/x) + g(y)$, then $\psi_y = -x^2/y^2 + x/(x^2+y^2) + g'(y) = x/(x^2+y^2) - x^2/y^2$, which means that $g'(y) = 0$, so we obtain that $g(y) = 0$ is acceptable. Therefore the solution is defined implicitly as $x^2/y + \arctan(y/x) = c$.

26. The equation is *homogeneous*. (See Section 2.2, Problem 30) We can write the equation in the form $y' = y/x + e^{y/x}$. We substitute $u(x) = y(x)/x$, which means $y = ux$ and then $y' = u'x + u$. We obtain the equation $u'x + u = u + e^u$, which is a separable equation. Separation of variables gives us $e^{-u}du = (1/x)dx$, so after integration we obtain that $-e^{-u} = \ln|x| + c$ and then substituting $u = y/x$ back into this we get the implicit solution $e^{-y/x} + \ln|x| = c$.

27. The equation can be made *exact* with an appropriate integrating factor. Algebraic manipulations give us the symmetric form $xdx - (x^2y + y^3)dy = 0$. We can check that $(M_y - N_x)/M = 2xy/x = 2y$ depends only on y, which means we will be able to find an integrating factor in the form $\mu(y)$. This integrating factor is $\mu(y) = e^{-\int 2ydy} = e^{-y^2}$. The equation after multiplication becomes

$$e^{-y^2}xdx - e^{-y^2}(x^2y + y^3)dy = 0.$$

This equation is exact now, as we can check that $M_y = -2ye^{-y^2}x = N_x$. Integrating M with respect to x gives that $\psi(x,y) = e^{-y^2}x^2/2 + g(y)$, then $\psi_y = -e^{-y^2}x^2y + g'(y) = -e^{-y^2}(x^2y + y^3)$, which means that $g'(y) = -y^3e^{-y^2}$. We can integrate this expression by substituting $u = -y^2$, $du = -2ydy$. We obtain that

$$g(y) = -\int y^3 e^{-y^2}dy = -\int \frac{1}{2}ue^u du = -\frac{1}{2}(ue^u - e^u) + c =$$

$$-\frac{1}{2}(-y^2e^{-y^2} - e^{-y^2}) + c.$$

Therefore the solution is defined implicitly as $e^{-y^2}x^2/2 - \frac{1}{2}(-y^2e^{-y^2} - e^{-y^2}) = c$, or (after simplification) as $e^{-y^2}(x^2+y^2+1) = c$. Remark: using the hint and substituting $u = x^2$ gives us $du = 2xdx$. The equation turns into $2(uy+y^3)dy = du$, which is a linear equation for u as a function of y. The integrating factor is e^{-y^2} and we obtain the same solution after integration.

28. The equation can be made *exact* by choosing an appropriate integrating factor. We can check that $(M_y - N_x)/N = (2-1)/x = 1/x$ depends only on x, so $\mu(x) = e^{\int(1/x)dx} = e^{\ln x} = x$ is an integrating factor. After multiplication, the equation becomes $(2yx+3x^2)dx + x^2dy = 0$. This equation is exact now, because $M_y = 2x = N_x$. Integrating M with respect to x gives that $\psi(x,y) = yx^2 + x^3 + g(y)$, then $\psi_y = x^2 + g'(y) = x^2$, which means that $g'(y) = 0$, so we obtain that $g(y) = 0$ is acceptable. Therefore the solution is defined implicitly as $x^3 + x^2y = c$.

29. The equation is *homogeneous.* (See Section 2.2, Problem 30) We can see that

$$y' = \frac{x+y}{x-y} = \frac{1+(y/x)}{1-(y/x)}.$$

We substitute $u = y/x$, which means also that $y = ux$ and then $y' = u'x + u = (1+u)/(1-u)$, which implies that

$$u'x = \frac{1+u}{1-u} - u = \frac{1+u^2}{1-u},$$

a separable equation. Separating the variables yields

$$\frac{1-u}{1+u^2}du = \frac{dx}{x},$$

and then integration gives $\arctan u - \ln(1+u^2)/2 = \ln|x| + c$. Substituting $u = y/x$ back into this expression and using that

$$-\ln(1+(y/x)^2)/2 - \ln|x| = -\ln(|x|\sqrt{1+(y/x)^2}) = -\ln(\sqrt{x^2+y^2})$$

we obtain that the solution is $\arctan(y/x) - \ln(\sqrt{x^2+y^2}) = c$.

30. The equation is *homogeneous.* (See Section 2.2, Problem 30) Algebraic manipulations show that it can be written in the form

$$y' = \frac{3y^2+2xy}{2xy+x^2} = \frac{3(y/x)^2+2(y/x)}{2(y/x)+1}.$$

Substituting $u = y/x$ gives that $y = ux$ and then

$$y' = u'x + u = \frac{3u^2+2u}{2u+1},$$

which implies that

$$u'x = \frac{3u^2+2u}{2u+1} - u = \frac{u^2+u}{2u+1},$$

a separable equation. We obtain that $(2u+1)du/(u^2+u) = dx/x$, which in turn means that $\ln(u^2+u) = \ln|x| + \tilde{c}$. Therefore, $u^2+u = cx$ and then substituting $u = y/x$ gives us the solution $(y^2/x^3) + (y/x^2) = c$.

31. The equation can be made *exact* by choosing an appropriate integrating factor. We can check that $(M_y - N_x)/M = -(3x^2+y)/(y(3x^2+y)) = -1/y$ depends only on y, so $\mu(y) = e^{\int(1/y)dy} = e^{\ln y} = y$ is an integrating factor. After multiplication, the equation becomes $(3x^2y^2 + y^3)dx + (2x^3y + 3xy^2)dy = 0$. This equation is exact now, because $M_y = 6x^2y + 3y^2 = N_x$. Integrating M with respect to x gives that $\psi(x,y) = x^3y^2 + y^3x + g(y)$, then $\psi_y = 2x^3y + 3y^2x + g'(y) = 2x^3y + 3xy^2$, which means that $g'(y) = 0$, so we obtain that $g(y) = 0$ is acceptable. Therefore the general solution is defined implicitly as $x^3y^2 + xy^3 = c$. The initial condition gives us $4 - 8 = c = -4$, and the solution is $x^3y^2 + xy^3 = -4$.

32. This is a *Bernoulli* equation. (See Section 2.4, Problem 27) If we substitute $u = y^{-1}$, then $u' = -y^{-2}y'$, so $y' = -u'y^2 = -u'/u^2$ and the equation becomes $-xu'/u^2 + (1/u) - e^{2x}/u^2 = 0$, and then $u' - u/x = -e^{2x}/x$, which is a linear equation. The integrating factor is $e^{-\int(1/x)dx} = e^{-\ln x} = 1/x$, and we obtain that $(u'/x) - (u/x^2) = (u/x)' = -e^{2x}/x^2$. The antiderivative of the function on the right hand side can not be expressed in a closed form using elementary functions, so we have to express the solution using integrals. Let us integrate both sides of this equation from 1 to x. We obtain that the left hand side turns into

$$\int_0^x (u(s)/s)'ds = (u(x)/x) - (u(1)/1) = \frac{1}{yx} - \frac{1}{y(1)} = \frac{1}{yx} - 1/2.$$

The right hand side gives us $-\int_1^x e^{2s}/s^2\,ds$. So we found that

$$1/y = -x\int_1^x e^{2s}/s^2\,ds + (x/2).$$

33. Let y_1 be a solution, i.e. $y_1' = q_1 + q_2y_1 + q_3y_1^2$. Let now $y = y_1 + (1/v)$ be also a solution. Differentiating this expression with respect to t and using that y is also a solution we obtain $y' = y_1' - (1/v^2)v' = q_1 + q_2y + q_3y^2 = q_1 + q_2(y_1 + (1/v)) + q_3(y_1 + (1/v))^2$. Now using that y_1 was also a solution we get that $-(1/v^2)v' = q_2(1/v) + 2q_3(y_1/v) + q_3(1/v^2)$, which, after some simple algebraic manipulations turns into $v' = -(q_2 + 2q_3y_1)v - q_3$.

34.(a) Using the idea of Problem 33, we obtain that $y = t + (1/v)$, and v satisfies the differential equation $v' = -1$. This means that $v = -t + c$ and then $y = t + (c-t)^{-1}$.

(b) Using the idea of Problem 33, we set $y = (1/t) + (1/v)$, and then v satisfies the differential equation $v' = -1 - (v/t)$. This is a linear equation with integrating factor $\mu(t) = t$, and the equation turns into $tv' + v = (tv)' = -t$, which means that $tv = -t^2/2 + c$, so $v = -(t/2) + (c/t)$ and $y = (1/t) + (1/v) = (1/t) + 2t/(2c - t^2)$.

(c) Using the idea of Problem 33, we set $y = \sin t + (1/v)$. Then v satisfies the differential equation $v' = -\tan t v - 1/(2\cos t)$. This is a linear equation with integrating factor $\mu(t) = 1/\cos t$, which turns the equation into

$$v'/\cos t + v\sin t/\cos^2 t = (v/\cos t)' = -1/(2\cos^2 t).$$

Integrating this we obtain that $v = c\cos t - (1/2)\sin t$, and the solution is $y = \sin t + (c\cos t - (1/2)\sin t)^{-1}$.

35.(a) The equation is $y' = (1-y)(x+by) = x + (b-x)y - by^2$. We set $y = 1 + (1/v)$ and differentiate: $y' = -v^{-2}v' = x + (b-x)(1+(1/v)) - b(1+(1/v))^2$, which, after simplification, turns into $v' = (b+x)v + b$.

(b) When $x = at$, the equation is $v' - (b+at)v = b$, so the integrating factor is $\mu(t) = e^{-bt-at^2/2}$. This turns the equation into $(v\mu(t))' = b\mu(t)$, so $v\mu(t) = \int b\mu(t)dt$, and then $v = (b\int \mu(t)dt)/\mu(t)$.

36. Substitute $v = y'$, then $v' = y''$. The equation turns into $t^2v + 2tv = (t^2v)' = 1$, which yields $t^2v = t + c_1$, so $y' = v = (1/t) + (c_1/t^2)$. Integrating this expression gives us the solution $y = \ln t - (c_1/t) + c_2$.

37. Set $v = y'$, then $v' = y''$. The equation with this substitution is $tv' + v = (tv)' = 1$, which gives $tv = t + c_1$, so $y' = v = 1 + (c_1/t)$. Integrating this expression yields the solution $y = t + c_1\ln t + c_2$.

38. Set $v = y'$, so $v' = y''$. The equation is $v' + tv^2 = 0$, which is a separable equation. Separating the variables we obtain $dv/v^2 = -tdt$, so $-1/v = -t^2/2 + c$, and then $y' = v = 2/(t^2 + c_1)$. Now depending on the value of c_1, we have the following possibilities: when $c_1 = 0$, then $y = -2/t + c_2$, when $0 < c_1 = k^2$, then $y = (2/k)\arctan(t/k) + c_2$, and when $0 > c_1 = -k^2$ then

$$y = (1/k)\ln|(t-k)/(t+k)| + c_2.$$

We also divided by $v = y'$ when we separated the variables, and $v = 0$ (which is $y = c$) is also a solution.

39. Substitute $v = y'$ and $v' = y''$. The equation is $2t^2v' + v^3 = 2tv$. This is a *Bernoulli* equation (See Section 2.4, Problem 27), so the substitution $z = v^{-2}$ yields $z' = -2v^{-3}v'$, and the equation turns into $2t^2v'v^3 + 1 = 2t/v^2$, i.e. into $-2t^2z'/2 + 1 = 2tz$, which in turn simplifies to $t^2z' + 2tz = (t^2z)' = 1$. Integration yields $t^2z = t + c$, which means that $z = (1/t) + (c/t^2)$. Now $y' = v = \pm\sqrt{1/z} = \pm t/\sqrt{t+c_1}$ and another integration gives

$$y = \pm\frac{2}{3}(t - 2c_1)\sqrt{t+c_1} + c_2.$$

The substitution also loses the solution $v = 0$, i.e. $y = c$.

40. Set $v = y'$, then $v' = y''$. The equation reads $v' + v = e^{-t}$, which is a linear equation with integrating factor $\mu(t) = e^t$. This turns the equation into $e^tv' + e^tv = (e^tv)' = 1$, which means that $e^tv = t + c$ and then $y' = v = te^{-t} + ce^{-t}$. Another integration yields the solution $y = -te^{-t} + c_1e^{-t} + c_2$.

41. Let $v = y'$ and $v' = y''$. The equation is $t^2v' = v^2$, which is a separable equation. Separating the variables we obtain $dv/v^2 = dt/t^2$, which gives us $-1/v = -(1/t) + c_1$, and then $y' = v = t/(1 + c_1t)$. Now when $c_1 = 0$, then $y = t^2/2 + c_2$, and when

$c_1 \neq 0$, then $y = t/c_1 - (\ln|1 + c_1 t|)/c_1^2 + c_2$. Also, at the separation we divided by $v = 0$, which also gives us the solution $y = c$.

42. Set $y' = v(y)$. Then $y'' = v'(y)(dy/dt) = v'(y)v(y)$. The equation turns into $yv'v + v^2 = 0$, where the differentiation is with respect to y now. This is a separable equation, separation of variables yields $-dv/v = dy/y$, and then $-\ln v = \ln y + \tilde{c}$, so $v = 1/(cy)$. Now this implies that $y' = 1/(cy)$, where the differentiation is with respect to t. This is another separable equation and we obtain that $cydy = 1dt$, so $cy^2/2 = t + d$ and the solution is defined implicitly as $y^2 = c_1 t + c_2$.

43. Set $y' = v(y)$. Then $y'' = v'(y)(dy/dt) = v'(y)v(y)$. We obtain the equation $v'v + y = 0$, where the differentiation is with respect to y. This is a separable equation which simplifies to $vdv = -ydy$. We obtain that $v^2/2 = -y^2/2 + c$, so $y' = v(y) = \pm\sqrt{c - y^2}$. We separate the variables again to get $dy/\sqrt{c - y^2} = \pm dt$, so $\arcsin(y/\sqrt{c}) = t + d$, which means that $y = \sqrt{c}\sin(\pm t + d) = c_1 \sin(t + c_2)$.

44. Set $y' = v(y)$. Then $y'' = v'(y)(dy/dt) = v'(y)v(y)$. We obtain the equation $v'v + yv^3 = 0$, where the differentiation is with respect to y. Separation of variables turns this into $dv/v^2 = -ydy$, which gives us $y' = v = 2/(c_1 + y^2)$. This implies that $(c_1 + y^2)dy = 2dt$ and then the solution is defined implicitly as $c_1 y + y^3/3 = 2t + c_2$. Also, $y = c$ is a solution which we lost when divided by $y' = v = 0$.

45. Set $y' = v(y)$. Then $y'' = v'(y)(dy/dt) = v'(y)v(y)$. We obtain the equation $2y^2v'v + 2yv^2 = 1$, where the differentiation is with respect to y. This is a *Bernoulli* equation (See Section 2.4, Problem 27) and substituting $z = v^2$ we get that $z' = 2vv'$, which means that the equation reads $y^2z' + 2yz = (y^2z)' = 1$. Integration yields $v^2 = z = (1/y) + (c/y^2)$, so $y' = v = \pm\sqrt{y + c}/y$. This is a separable equation; separating the variables we get $\pm ydy/\sqrt{y + c} = dt$ and then the implicitly defined solution is obtained by integration: $\pm(\frac{2}{3}(y + c)^{3/2} - 2c(y + c)^{1/2}) = t + d$.

46. Set $y' = v(y)$. Then $y'' = v'(y)(dy/dt) = v'(y)v(y)$. We obtain the equation $yv'v - v^3 = 0$, where the differentiation is with respect to y. This separable equation gives us $dv/v^2 = dy/y$, which means that $-1/v = \ln|y| + c$, and then $y' = v = 1/(c - \ln|y|)$. We separate variables again to obtain $(c - \ln|y|)dy = dt$, and then integration yields the implicitly defined solution $cy - (y\ln|y| - y) = t + d$. Also, $y = c$ is a solution which we lost when we divided by $v = 0$.

47. Set $y' = v(y)$. Then $y'' = v'(y)(dy/dt) = v'(y)v(y)$. We obtain the equation $v'v + v^2 = 2e^{-y}$, where the differentiation is with respect to y. This is a *Bernoulli* equation (See Section 2.4, Problem 27) and substituting $z = v^2$ we get that $z' = 2vv'$, which means that the equation reads $z' + 2z = 4e^{-y}$. The integrating factor is $\mu(y) = e^{2y}$, which turns the equation into $e^{2y}z' + 2e^{2y}z = (e^{2y}z)' = 4e^y$. Integration gives us $v^2 = z = 4e^{-y} + ce^{-2y}$. This implies that $y' = v = \pm e^{-y}\sqrt{c + 4e^y}$. Separation of variables now shows that $\pm e^y dy/\sqrt{c + 4e^y} = dt$ and then $\pm\frac{1}{2}(c + 4e^y)^{1/2} = t + d$. Algebraic manipulations then yield the implicitly defined solution $e^y = (t + c_2)^2 + c_1$.

48. Suppose that $y' = v(y)$ and then $y'' = v'(y)v(y)$. The equation is $v^2v' = 2$,

which gives us $v^3/3 = 2y + c$. Now plugging 0 in place of t gives that $2^3/3 = 2 \cdot 1 + c$ and we get that $c = 2/3$. This turns into $v^3 = 6y + 2$, i.e. $y' = (6y + 2)^{1/3}$. This separable equation gives us $(6y + 2)^{-1/3} dy = dt$, and integration shows that $\frac{1}{6}\frac{3}{2}(6y + 2)^{2/3} = t + d$. Again, plugging in $t = 0$ gives us $d = 1$ and the solution is $(6y + 2)^{2/3} = 4(t + 1)$. Solving for y here yields $y = \frac{4}{3}(t + 1)^{3/2} - \frac{1}{3}$.

49. Set $y' = v(y)$. Then $y'' = v'(y)(dy/dt) = v'(y)v(y)$. We obtain the equation $v'v - 3y^2 = 0$, where the differentiation is with respect to y. Separation of variables gives $vdv = 3y^2 dy$, and after integration this turns into $v^2/2 = y^3 + c$. The initial conditions imply that $c = 0$ here, so $(y')^2 = v^2 = 2y^3$. This implies that $y' = \sqrt{2}y^{3/2}$ (the sign is determined by the initial conditions again), and this separable equation now turns into $y^{-3/2} dy = \sqrt{2} dt$. Integration yields $-2y^{-1/2} = \sqrt{2}t + d$, and the initial conditions at this point give that $d = -\sqrt{2}$. Algebraic manipulations find that $y = 2(1 - t)^{-2}$.

50. Set $v = y'$, then $v' = y''$. The equation with this substitution is

$$(1 + t^2)v' + 2tv = ((1 + t^2)v)' = -3t^{-2}.$$

Integrating this we get that $(1 + t^2)v = 3t^{-1} + c$, and $c = -5$ from the initial conditions. This means that

$$y' = v = 3/(t(1 + t^2)) - 5/(1 + t^2).$$

The partial fraction decomposition of the first expression shows that $y' = 3/t - 3t/(1 + t^2) - 5/(1 + t^2)$ and then another integration here gives us that $y = 3 \ln t - \frac{3}{2} \ln(1 + t^2) - 5 \arctan t + d$. The initial conditions identify $d = 2 + \frac{3}{2} \ln 2 + 5\pi/4$, and we obtained the solution.

51. Set $v = y'$, then $v' = y''$. The equation with this substitution is $vv' = t$. Integrating this separable differential equation we get that $v^2/2 = t^2/2 + c$, and $c = 0$ from the initial conditions. This implies that $y' = v = t$, so $y = t^2/2 + d$, and the initial conditions again imply that the solution is $y = t^2/2 + 3/2$.
